In closing this question of treatment, may I reiterate the feeling, which grows stronger the wider the experience, that it is impossible to expect the best results in dealing with this, as well as other stomach diseases, from purely special methods of treatment. The debt which we owe to those who have specialized in gastric diseases is immense, but the long-continued study of cases shows that, while we should avail ourselves of the art of the specialist, we can not dispense with the wide knowledge of general pathology and therapeutics which is the possession of the high-class general practitioner.

DISCUSSION.

ON PAPERS OF DRS. BILLINGS, DOCK, MUSSER AND STOCKTON.

Dr. Richard C. Cabot, Boston, asked Dr. Stockton on what grounds he would be willing to state, in any case, that there is an abnormal amount of mucus in the stomach contents. He also asked Dr. Musser if he could give any figures showing what proportion of all cases coming to him with stomach symptoms really have stomach disease.

Dr. G. W. McCaskey, Fort Wayne, Ind., declared that to say that in a certain sense the disorders of the stomach are fundamentally more important than those of other organs of the body is to utter the merest platitude. Gastric disease frequently stands in causal relationship to a large group of diseases, renal disease being among them. It is true that perhaps in the majority of such cases the intestines are the organs directly at fault; but if one traces the causes further back the ultimate cause will frequently be found to arise in gastric disease. Dr. McCaskey believes this to be true in a very large proportion of the cases. Abnormal gastric conditions may lead to imperfect intestinal function. He emphasized in particular the necessity of a thorough comprehension of the physiology of the stomach before attempting to understand its diseases. This is not peculiar to the stomach, but in no other organ is it more fittingly illustrated. If, for instance, certain well-known facts regarding the physiology of the stomach had been taken into consideration, the dictum that the presence of hydrochloric acid excluded cancer would never have been made. There can be advanced cases of cancer of the pylorus (in which there are no acid-forming cells) without any diminution of the secretion of hydrochloric acid; in fact, it is liable to be increased at first as a result of the stimulation of the organ by the neoplasm. Many such cases have been reported, and Dr. McCaskey added one to the list within the last few months.* It seems to him that exaggerated conclusions have been drawn during the past few years in papers which have appeared on the subject of food stagnation. In one, for instance, an attempt was made to set the limit of twelve hours beyond which limit if food was found it indicated organic disease, in which operative interference was to be considered. In Dr. McCaskey's opinion much severer grades of gastric myasthenia are amenable to medical treatment. He is in accord with the conservative position taken by Dr. Stockton. Dr. McCaskey has found in a large proportion of the cases that intragastric cold douches do not agree with the patients. He does not know precisely why, but possibly it is because of the close proximity of the stomach to the solar plexus, or perhaps some peculiar susceptibility of the nervous organization of the stomach to the depressing action of cold. The importance of stomach analyses appears to him to be very great, and he endorsed and emphasized practically all that Dr. Dock has said. The recent attempts to belittle gastric chemistry are not well founded and are greatly to be deplored. He differed with Dr. Dock in the use of the Gunsberg reagent as a qualitative test for free HCl. He considers a 1 per cent. solution of resorcin much preferable because of its greater stability. Its delicacy is precisely the same, but no greater than that of the Guenžburg reagent. The questions of general nutrition discussed by Dr. Billings are of vital importance from the practical quite as much as the theoretical point of view. The problems of proteid metabolism are exceedingly difficult, and as yet are impossible of full solution. It seems quite probable that the existing dietetic standard with relation to proteid intake is somewhat too high, but just how much does not seem to Dr. McCaskey to be established. There is no doubt, however, that the nitrogen balance can be maintained and the organism kept in good working condition on much less than that indicated by the Voit standard, but it seems that we are not at present justified in accepting a standard less than 80 grams of proteid per diem for the average individual of about 150 pounds weight. The investigations of Richardson and Folin are suggestive in the highest degree, even if their conclusions are not final, as it seems to Dr. McCaskey that the time over which the experiments ranged, even though of several months' duration, is not long enough to give final results. Even though body weight is maintained at a slightly lower level than before, and the working capacity of the individual remains up to the average, there are still other questions unanswered: the resistive power, for instance, of the individual to morbific influences; and the problem may even go further and be racial in its character. One fact should be clearly emphasized, and that is that the proteid intake should not vary with muscular exercise to the same extent as the carbohydrates. The latter are the force-producing, dynamic portion of the diet, and the quantity should rise and fall with the amount of muscular work done. The laboring man needs more starch and sugar and fat, but not necessarily a great increase in meat or other proteid foods.

Dr. Morris Manges, New York, said that the average general practitioners do not make extensive use of the valuable means of diagnosis at their disposal. Again, when such attempts are made, often the method is at fault, and especially is this true when an attempt is made to pass the stomach tube. Very often failure results because of the nature of the tube; the majority of these tubes are soft, and really can not be used by any one, and are often provided with a bulbous funnel at the ends. Another point is the awkwardness of the manipulator, possibly from lack of practice. As a result of all this, the general practitioner believes that these various methods of diagnosis and analyses of stomach contents, are too complex, though they are even simpler than the methods employed for urinary analyses. One need not bother with percentages; one only requires average figures. We must know relatively the presence or absence of free hydrochloric acid, etc. Another point Dr. Menges believes to be of importance is that what little of the stomach contents is found on the end of the tube can be utilized for diagnosis; no matter how small, strips of testing paper can be used by applying them to the end of this tube, and a complete analysis can be made. The futility of making one analysis should be emphasized. If we are dealing with organic disease the variations presented can only be appreciated by those who have worked with these tests; the use of one test breakfast will not do. It is positively absurd, he said, to depend on the results of one examination. By gross examinations of specimens one can determine a great deal in the vast majority of clinical cases.

Dr. S. P. Black, Pasadena, called attention to an important point brought out by Dr. Billings, i. e., the question of proper mastication. We all know that mastication is improperly performed by all of us; if more time were devoted to proper mastication there would be far less bolting of food. When exercise is taken a meat diet is needed. It is necessary that mastication should be so complete that the gastric and intestinal juices may gain ready access to all particles of the food. If mastication is properly and thoroughly done, the appetite can be satisfied with a less amount of food. More that is taken in can be utilized and less will be excreted. The amount of food taken depends on so many conditions that it is difficult to state exactly the amount necessary for each. This varies with the period of life and many other factors. For instance, an old man can not take the same amount of food that a younger man can. It should be borne in mind that the majority of cases of chronic rheumatism are due to a toxemia from the decomposition of proteids. The excess of proteid material appears not only in the form of urea and other products, but also as ptomains which when absorbed give rise to chronic joint affections. The relation, therefore, between proteid intake and mastication can readily be seen and its importance recognized. Dr. Black quoted Dr. Stengel as saying that there exists a feeling among the profession that the examination of the secretion of the stomach is becoming of less and less importance and that an examination to determine the motor function of this organ is of prime importance. The papers read in this symposium place more reliance on the physiology of the stomach and a study of the stomach secretion. The laboratory is essential for a proper understanding of abnormal gastric diseases.

---

* The Journal A. M. A., April 1, 1905.

Dr. Joseph L. Miller, Chicago, asked what results Dr. Dock has had with Weber's test for blood in the stomach contents and what value he places on it. While it is true, Dr. Miller said, that in cases in which hydrochloric acid is present it is not absolutely necessary to test for pepsin, still in those cases in which there is an absence of hydrochloric acid it is necessary to determine whether pepsin is absent as well. He asked Dr. Dock if he resorts to this test. Dr. Miller believes this test should be in more general use. He believes that we should simplify exact qualitative determination more than we at present do. On the other hand, he also believes that a quantitative determination gives very valuable information. With Ewald's aspirator it is very easy to obtain all the contents of the stomach, and the use of this instrument simplifies the methods very much. When sarcinæ are associated with a marked increase in the hydrochloric acid, it is important as indicating a benign stenosis of the pylorus.

Dr. J. M. Anders, Philadelphia, said that it is a well established fact that physiology has a direct bearing on practice of medicine and is a most valuable aid in recognizing and treating diseased conditions. The only defect in this symposium is that the physiology of digestion has not been included. The distribution of copies of papers such as presented by Dr. Billings would have a decided effect on medical progress in America. What Dr. Billings has given us is beyond dispute, and these things are most useful to the practicing physician. Dr. Anders was glad to hear him mention and emphasize the fact that the average amount of food ingested is at least twice as much as required to maintain complete physiologic efficiency. The minimum amount of alimentation necessary under the many varying conditions of life, including the ages of patients, is as yet imperfectly understood. The physician should be able, instead of as at present estimating empirically how much food is necessary, to determine this scientifically. The medical profession certainly owes much to the observations of Chittenden, Voit, Atwater and others. The determination of the amount of creatinin excreted daily is sufficient for the determination of the nitrogen balance of the body. Dr. Anders believes that up to the present time, and in the future as well, the most important advances will be those made as the result of analyses of food ingested and the urine, the feces, etc., excreted. In addition, it is necessary to take into consideration other factors, such as the influence of exercise, sleep and baths. These problems of nutrition seem somewhat complex, more than certain observers would have us believe. Dr. Musser has presented a long list of factors in which gastric symptoms are present, but Dr. Anders would be glad to hear more regarding acute symptoms that occur in chronic affections and which are apt to mislead us. Recently Dr. Anders saw a patient suffering from acute articular rheumatism, in whom the joint condition was held in abeyance with the distension of the stomach. It was thought that gastric trouble had developed, but the physical examination revealed the presence of a pericarditis. He has seen several similar instances with pain in the epigastrium. He was very glad to hear Dr. Dock emphasize the variability which resulted from an examination of the gastric contents. It should be borne in mind, however, that no organic affection of the stomach exists, but that it presents certain variabilities, although such changes are by no means pronounced in all instances.

Dr. F. C. Shattuck, Boston, declared that there is too much theory regarding this matter. He believes that medical men are in danger of running after false gods. There are, he believes, but two conditions in connection with ulcer which call for surgery. The first is perforation; the other, obstinate cicatricial contraction of the pylorus.

Dr. James J. Walsh, New York, said that in stomach medication the nostrums have even a larger field than in any other disease. Judging from the number of varying remedies for stomach symptoms of all kinds that are fairly pushed on the doctor by the advertising agents and the large amount of printed matter with regard to them that comes to his table, there must be an immense amount of medicine for stomach symptoms prescribed in this country. All sorts of ferments have been introduced and all the vegetable kingdom has been rifled of precious treasures in order to provide new stomachics. The more distant the country and the more unusual the plant from which they come the more grandiloquent the advertising and the greater the promise of efficiency. Josh Billings once said that it is not so much the ignorance of mankind that makes them ridiculous as the knowing so many things that ain't so, and there is no doubt that with regard to our knowledge of the stomach this is truer than with regard to almost any other department of medicine. Each individual is absolutely a law unto himself as regards his tastes and his capacity for digesting various articles. The distinguished Russian physiologist, Pawlow, has demonstrated that in animals at least a special kind of gastric juice is secreted for each kind of food that the animal takes. If to this be added the individual tastes in human beings and the psychic influence on the stomach, then the problem of stomach digestion becomes the most complex we know. Fortunately physicians do not have to bother much about the variations in the chemism of the stomach. So long as the stomach will pass on the food that is furnished it digestion will go on and will maintain nutrition. In cases of gastric cancer, for which the whole organ is removed, it is a common experience that the patients gain as much as 30 or 40 pounds in weight within a few months after the operation, in spite of the complete removal of their stomachs. This, however, is only a confirmation of what was known otherwise as the result of stomach investigation. Not a few persons suffer from achylia gastrica, that is, a condition in which there is no secretion of gastric juice in the stomach and no process of digestion carried on there, yet suffer very little from digestive symptoms and do not lose in weight. In more recent times the practice of jejunostomy has demonstrated the same thing. When there is a cancer of the pylorus and the patient has lost seriously in weight, digestion proceeds very happily and nutrition begins at once to improve when an opening is made by which food is allowed to pass on immediately to the intestines. Gastric motility, then, is more important than gastric chemism. If physicians can only switch the food past the stomach, the digestive system will continue its work. As a matter of fact, most of the tonics that do good in digestive disturbances influence the motility of the stomach rather than its secretory activity. That is why strychnin is so useful. The most serious difficulty that hampers stomach motility is the lack of proper mastication. Meats must be chewed, but still more must vegetables be chewed. It is the vegetable-eating animals that ruminate. It is in this line and not in trying to help gastric chemism and the ferments that therapeutics are effective.

Dr. John A. Lichty, Pittsburg, believes that gastric atony due to organic obstruction is the crucial point in this symposium and that it will assume the same position in the next few years in the deliberations of this section that appendicitis did some years ago. After a rather extensive experience in the treatment of these conditions, he has found that in many cases he might have easily dispensed with mechanical devices, such as intragastric electricity, massage and lavage. Simply advising the patient to masticate his food more thoroughly and to refrain from drinking at meals and for an hour or two after seemed to be all that is necessary in many cases. Food not properly masticated must be ground up in the pyloric end of the stomach, and such extra work is likely to produce atony, erosion, ulceration or other gastric disturbances. Dr. Lichty did not mean to say that we should not use these agents in selected cases, for they are often absolutely essential to bring about a curve. *In the treatment of gastric atony due to organic obstruction,* the internist and surgeon must come together and understand each other. The earlier this is done the better for the patient's welfare. With the present methods of diagnosis physicians are not yet able to make a definite diagnosis in the earlier stages of some of the most important gastric lesions. The effect of rational treatment and the course of disease must be observed at times before a diagnosis can be made. Now and then it may be necessary to do an exploratory operation before a diagnosis can be made. Such an operation is not always a serious undertaking and may frequently reveal important conditions. Dr. Lichty recently saw a case in which he was positive that there was a gastric ulcer; the patient suddenly had an attack of jaundice and then he was positive that he had to deal with a case of obstruction of the gall ducts. There was found at operation a band of adhesion which interfered with the pyloric entrance and also with the gall duct. No amount of treatment would have relieved this patient, though she had received treatment from different physicians for a year or more for gastric ulcer and for gallstones. The tendency of the internist too often is to be satisfied to have patients in a chronic condition come to the office day after day until they are entirely dissatisfied and discouraged and ready to desert to the quack. There is still too wide a space between the internist and the surgeon, and in this space the quack and unscrupulous doctor find a rich harvest. The internist and surgeon must co-operate.

Dr. C. M. Cooper, San Francisco, said that Dr. Billings' paper should have been read before a conjoined section, inasmuch as the subject matter is unwisely neglected and its importance to all branches is equally great. It is not necessary to tell the patient to limit the intake, as the muscular movements associated with thorough chewing plus the better digestion of the food chewed induce a feeling of satisfaction which in itself tends to diminish the amount eaten. Further, it must be remembered that a thorough clinical examination should come before a chemical analysis of the stomach contents. On the Pacific slope aneurism is so common—abdominal aneurism as well as thoracic—that such an inverted order of examination might lead to serious trouble. Moreover, frequent chemical examinations are just as important as frequent stomach-content analyses. If prior to the passing of the stomach tube the patient suck a strong English peppermint the throat is partially anesthetized and the proceeding is rendered less difficult in sensitive patients. Though, of course, periodic gastric crises may occur in locomotor ataxia and be due to that alone, sometimes there is a local trouble underlying or complicating the nerve storms, as in two cases which Dr. Cooper recently saw. In one there was stenosis of the pylorus; in the other, a band binding down the first part of the duodenum was demonstrated by operation. The great majority of physicians refer their gastric patients too late to the surgeons and terminal infections occur. Patients should be referred back to the physician; otherwise the primary constitutional tendencies which have led to secondary lesions necessitating surgical interference will often remain uncorrected.

Dr. Norman Bridge, Los Angeles, Cal., said that one important point in the physiology of the stomach has been omitted in this discussion, and that if physicians could keep this point in mind it would simplify the subject very much. The stomach is not useful in absorption. The important thing regarding this organ is its motility, and the purpose of the stomach seemed to be to act as a reservoir to receive and to retain food for a variable period of time and to deliver it slowly to the intestine. The stomach could be left out of consideration for the business of digestion. If we could get the food out of the esophagus, through the pylorus, it then would be possible sufficiently to nourish patients. The absorption of water even does not take place to any extent from the stomach. It is a convenience to mankind to take food into the stomach at certain intervals and to go on about the business of life. If one takes too much food and absorbs too much, it is the intestines that do it and not the stomach at all. Dr. Bridge thinks that it can be shown that the stomach may directly cause such systemic diseases as Dr. McCaskey has referred to.

Dr. Frank Billings, Chicago, stated that carbohydrates and fats furnish the animal body fuel. The proteid food furnishes the defect due to waste of the muscular system and other organs which perform the work for the body. The amount of carbohydrates and fats necessary for fuel for an adult will depend on the character of the work. A laboring man will require more than a man who leads a sedentary life. The amount of proteid necessary to repair the waste from muscular exertion, etc., has been found to be only about one-half that which has been advocated for years in the standard dietaries. With this one-half the amount of proteids a nitrogenous balance may be maintained. There are fanatics on all subjects, and in this particular one those who advocate a very low proteid intake and over-mastication, as compared with ordinary chewing of food, may do things which appear ridiculous. Nevertheless, the action of these men and what has been written on the extreme side of the question by them has brought the attention of the public to the subject and in this way has been of great benefit. The lay public and many of the medical profession believe that all strength, nutrition and force comes from the proteids and especially from the albumin of meat. The fact is that the proteid is simply a tissue builder, and growing individuals, therefore, may require a considerable amount of albumin, but when the growth is once attained only that amount of proteid will be necessary to maintain good health and strength which will furnish food to take the place of the waste produced by muscular and other bodily activities. The amount of proteid necessary for each individual may differ, but only that amount will be required which will maintain a nitrogenous balance, as evinced by the nitrogenous output in the urine, feces, etc. Dr. Billings mentioned an error which may occur from the use of bread in a test meal. Sponge bread so used, even after twenty-four or more hours old, will show yeast cells in the stomach contents and may, therefore, be misinterpreted as indicating stasis of the stomach contents.

Dr. George Dock, Ann Arbor, said that he considers visible masses of mucus in the stomach contents as abnormal, but one must be sure this mucus does not come from the respiratory tract or from the mouth or be the result of awkward manipulation of the tube. On the other hand, a small amount of mucus which is visible may be present, and yet one can not say from this alone that the patient has chronic gastritis. Though the physician can not draw the line anywhere, Dr. Dock would say that in general more than from 3 to 5 c.c. is abnormal. He agreed that resorcin is an excellent test, but he likes Günsburg's better. He also agreed that not too much time should be spent in working with the decinormal solutions, etc.; but, on the other hand, a physician should have had practice with these before doing more rapid work. The examination of the vomitus he believes to be very important, but he sounded a note of warning against the use of this method as a substitute for the tube; it is a dangerous one. A patient can vomit a large quantity and yet the stomach contain still more important material. Dr. Dock has been using tests for occult blood in the laboratory, and with satisfaction. He has also looked for occult blood in the stools after excluding any bleeding points in the rectal mucosa. Delicate reactions for blood in stomach contents are easy, but one may meet with many instances in which there is no distinct lesion of the mucous membrane. He agreed with Dr. Miller regarding the test for pepsin and also for rennin. They are useful, but one can very often get along without either of them. The presence of sarcinæ gives valuable information in many ways. Sarcinæ are rarely found in malignant disease of the stomach. If found in large quantities it is sufficient to say that the patient has not malignant stomach disease. On the other hand, yeast is often found in gastric cancer when hydrochloric acid is still present. He is not so enthusiastic with regard to the surgery of the stomach as Dr. Walsh. He agreed that cancer should be operated on if possible. In cases of ulcer, also, he has had patients operated on and with good results. But doing a gastroenterostomy in case of ulcer does not make the patient normal. In a large number of patients, 16 or 17, who have been reported as being operated on for gastric ulcer, peptic jejunal ulcers have developed which were even more dangerous than the original gastric ulcer. This ulcer tendency can not be cured by operation, and so it is with functional disease and stagnation of food; it has not been demonstrated in cases of gastroenterostomy or pyloroplasty that the stomach is as good as before. Therefore, he thinks, physicians should take the middle ground between what Dr. Walsh has given us and those who take the gloomy aspect or conservative aspect in regard to this subject.

Dr. Charles G. Stockton, Buffalo, thinks that lack of success is often due to the way in which cold is employed. If too cold, or if too much force is employed, depression is likely to follow. Sometimes benefit is to be obtained by alternating the cold with the hot douche. He also emphasized what Dr. Manges said regarding the importance of selecting a proper stomach tube. This is a point that is often overlooked. He also agreed with Dr. Lichty that in the treatment of stagnation, which depends on atony rather than on obstruction, much can be accomplished in attention to mastication and the withholding of liquids at meals. In any case of atony of the stomach reaching to stagnation, without obstruction, one should not forget what can be accomplished through the general management of the case and general measures. He advised physicians not to overlook general innervation. On the other hand, he said one often fails to obtain success because of overlooking local treatment. He disagreed with Dr. Bridge that the stomach is practically unnecessary. Physicians are too prone to say that certain organs are unnecessary to-day. He does not believe that one can get along without the stomach, even if anastomosis is practicable. In some cases of achylia gastrica the stomach will empty itself quickly, within ten minutes after a meal is taken, thus showing an enormous motor activity. This state may be compared to that of the patient without a stomach. Yet these cases of achylia gastrica have general and local symptoms and the victims are not well people.

A CASE OF HEART GUMMATA, WITH SUDDEN DEATH.*

F. GOLDFRANK, M.D.
NEW YORK.

On Jan. 10, 1905, Professor Dittrich, head of the Department of Legal Medicine in the German University in Prague, performed an autopsy on a woman aged 25, who had died suddenly during the night of January 8. The report from the police department stated merely that the woman had "heart disease" for some time. The heart revealed such an interesting condition that Professor Dittrich at once sent it to the pathologic institute for further study.

AUTOPSY REPORT.

The findings at the autopsy, according to the data kindly furnished by Professor Dittrich, were, briefly, as follows:

General Appearance.—The body was of medium height, stout but well built and well nourished. The brain was normal, somewhat anemic. The lungs were perfectly normal, no sign of tuberculosis being found; some of the bronchial lymph glands, however, showed the presence of calcified nodules. The liver and spleen were hyperemic, otherwise normal. The gastrointestinal tract, pancreas, adrenals, and the bones were normal.

Kidneys.—The right kidney likewise showed no pathologic changes. The left kidney, which was received with the heart, presented two deep cicatricial depressions. One of these embraced the posterior surface and outer border near the lower pole, and measured 4 cm. by 2 cm. On section, a mass of firm gray scar-like tissue was seen extending deep into the substance of the kidney. This mass appeared to consist of numerous distinct nodules of varying size, the largest 6 mm. in diameter. These tended to form a conglomerate and, on the other hand, were not very sharply separated from the kidney substance. Near the conglomerate, but separated from it by renal tissue, were several small nodules. The second depression was situated on the posterior surface of the kidney near the upper pole. It was much larger, measuring 6 cm. in each direction; but it did not extend deeply into the kidney, and showed no nodules.

Pelvis.—The urinary bladder was normal. The vagina and the somewhat enlarged uterus contained a small amount of white tenacious mucus. The uterine adnexa were firmly adherent to the surrounding tissues, and both tubes were dilated with a watery fluid to the size of a little finger. The ovaries contained a number of cysts, some of them filled with a bloody fluid.

Heart.—The pericardial cavity contained a small amount of clear serum. Over an area of 6 sq. cm. on the anterior surface of the lower third of the left ventricle the two pericardial layers were adherent. Otherwise, the pericardium was normal with the exception of a thickened and reddened area over the left auricular appendix. The heart was markedly enlarged, especially the left ventricle. The cause of this latter was discovered on opening the heart, for practically the entire wall of the left ventricle was infiltrated or substituted by a huge mass of firm grey white tissue similar to that seen in the kidney. This mass, projecting far into the lumen of the ventricle, presented an irregularly and coarsely nodular surface. In the opposite direction it extended in some places as far as the pericardium, in others it was separated from the latter by the hypertrophied muscle, which averaged 14 mm. in thickness. Only one area of the left ventricle was free from this tumor mass, a space measuring irregularly 6 by 2.5 cm. embracing the lower part of the septum and the adjoining portion of the anterior surface. The entire ventricle was over 10 cm. in length and 7 cm. in lateral diameter. The thickest part of the wall along the left border measured 4 cm., of which 2.5 cm. was composed of tumor. The growth had completely infiltrated the papillary muscles as well as the lateral half of the auriculoventricular ring, where a nodule of 4 cm. in diameter projected into the left auricle. In the left auricular appendix were several smooth, grayish white patches. Furthermore, the tumor extended from the upper part of the ventricular septum into the lumen of the right ventricle. The latter had in addition several small nodules in the myocardium of its right border. The right auricle was not affected, and all four of the valves were normal in appearance. The foramen ovale was closed. In the heart cavities only fluid blood was found. The aorta was in general normal; only just above the aortic valve and in the arch were minute grayish yellow thickenings of the intima.

HISTORY OF CASE.

These findings appeared to justify a tentative diagnosis of a gummatous affection of the heart and kidney. Consequently, investigations were promptly begun as to the history of the case, and for the success of these researches I am indebted not only to Professor Chiari, who gave me most valuable assistance and advice throughout, but also to the painstaking investigation of privatdocent Dr. Ferdinand Pecirka, *Polizeichefarzt* in Prague. Further information was kindly furnished by Prof. Filip Josef Pick of the German dermatologic clinic, and Professor Janovsky of the Bohemian dermatologic clinic.

The history of the case is as follows:

Patient.—K. Z. was born in 1880. Her father is still living at the age of 62. He was formerly a soldier, has always been healthy though not robust, and has had numerous children from two marriages. The mother was an illegitimate child, had five children, and died at the age of 36. Further details about her are not known. The patient had none of the important diseases of childhood. On March 26, 1896, she applied for a license as prostitute. As, however, she had not at that time had any venereal trouble and further had not practiced prostitution regularly, her application was refused. On May 5, she again applied with the statement that she had been treated for gonorrhea and a soft chancre. The license was then granted. Her statement was accurate, since she had actually been in Prof. Janovsky's clinic from April 4 till May 5. The diagnosis was *Ulcus molle commissuræ. Blennorrhœa chronica urethræ et cervicis.* Gonococci were present. There were no general symptoms.

Clinical History.—On Oct. 9, 1896, she entered Professor Pick's clinic with the clinical diagnosis *"Lues condylomatosa."* At that time she presented a general maculopapular skin eruption; squamous eruption on the palms; ulcerated mucous patches in the mouth, on the palate, and tonsils; syphilitic leucoderma; erosions on the caruncula, on the posterior wall of the vagina, and on the vaginal portion of the cervix; and finally a urethritis. During her stay in the clinic she had an attack of catarrhal icterus. On November 25 she was discharged "free from symptoms." In March, 1897, she was again in Prof. Janovsky's clinic for three weeks, where she was treated with three injections of salicylate of mercury. The diagnosis read: *Lues condylomatosa. Leucoderma Neisser. Blennorrhœa cervicalis.* (Gonococci positive.) Finally, in September, 1897, she remained sixteen days in Prof. Janovsky's clinic, receiving two potassium iodid injections. At this time, in addition to a venereal ulcer, cervical gonorrhea, and leucoderma, she had a general glandular enlargement. There were no local symptoms of syphilis.

---

* From Professor Chiari's Pathologic Institute in Prague.

Subsequent History.—In 1899, she applied for a revocation of her license on the ground that she was entering domestic service. She continued her former profession however, in combination with that of waitress. In September, 1903, she married a student who readily admitted that his wife had had an "intimate friendship" with numerous other students. Soon after their marriage, she was examined by the physician of a life insurance company and rejected on the ground that she had a heart lesion. Neither before that time nor afterward, however, had she had the slightest symptoms of a disease of the heart, being always in the best of health. She was likewise rejected by a second insurance company for the same reason. Of the presence of heart symptoms immediately preceding the sudden death no information could be obtained.

The foregoing facts establish beyond question that the woman had become infected with syphilis eight and a half years before her death, and almost as certainly that she had some heart lesion for one year. Further, that the latter caused no symptoms sufficiently marked to be noted by her or by those immediately about her.

VERIFICATION OF DIAGNOSIS.

Parallel with the investigations into the antecedents of the patient, the microscopic examination of the heart and kidney was undertaken in order to verify the gross diagnosis. From the heart, pieces were taken from the wall of the left ventricle, the papillary muscles, the septum, and the left auricle. Both areas in the kidney were also examined. The pieces were fixed in Orth's fluid, and stained with hematoxylin-eosin, Van Gieson's solution, Weigert's resorcin-fuchsin, for tubercle bacilli, and for fibrin. I may say here that a careful search for tubercle bacilli was negative throughout. The gross specimens were preserved in alcohol for the pathologic museum of the institute.

Microscopic Examination.—As typical of the various places examined, a section extending through the wall of the left ventricle from the pericardium to the trabeculæ and endocardium may be considered. At this place the heart wall was 3.5 cm. thick, and of this about 1 cm. nearest the pericardium showed the regular arrangement of heart muscle. The rest of the section contained only one muscular bundle of considerable size. With this exception, there were no traces of muscular fibers till the outer half was reached, where a few fibers appeared here and there, and then rapidly increased in number as the muscular zone was approached. In other words, there was no sharp line of demarcation between myocardium and tumor; the latter extended in an infiltrating manner between the muscle fibers. Of the tumor, a portion consisted of a poorly stained, partly homogeneous, partly reticulated ground substance, which was either free from cellular elements or contained scattered fragments of nuclei. These necrotic areas were not sharply circumscribed, but passed over gradually into places where the reticular substance was interspersed with numerous cells, and then into other parts where the latter predominated to the almost complete exclusion of intercellular substance. In the less cellular places there were occasional collections of cells which appeared fairly circumscribed with the lower power, although they were irregular, not rounded in outline.

The character of the cells was varied. The greater number were small, with a round, deeply staining nucleus and very little protoplasm, corresponding to the small lymphocytes of the blood. Most of the remaining cells were small spindle cells of the type found in young connective tissue. Also where these predominated there was a certain amount of intercellular connective tissue consisting of fine fibers and a somewhat coarser network, which, however, was nowhere very dense. Cells with a small round eccentric nucleus and a fairly large amount of slightly eosinophile protoplasm (plasma cells) were numerous in almost every field. "Epithelioid" cells were much less widely distributed; polymorphonuclear leucocytes were virtually absent.

A study of the arrangement of the cells revealed nothing that was at all constant. Certainly there was no distinct zone of epithelioid cells around the central necrotic areas; here and there a few such cells were grouped together near the latter. In general, the lymphocytes, plasma cells, and fibroblasts were interspersed without special arrangement. Only in the circumscribed cellular foci referred to above was there a definite structure. Here there were usually a number of fibroblasts in the center or immediately about a small necrotic center, and around these a dense zone of lymphocytes, which then gradually lessened in number toward the periphery. These areas, however, contained another type of cell, and that in no infrequent number. In the very center there was often a large giant cell of the Langhans type, and near this usually several smaller ones. In one field (Zeiss, oc. 2, obj. C.) there could be noted as many as seven unquestionable giant cells. It was only in these patches, however, that they were found.

The heart muscle cells, even at the very boundary of the tumor where individual cells were frequently isolated, showed a protoplasm of normal staining power and perfectly distinct striations. The nuclei also stained well and presented few signs of degeneration. At the boundary zone, however, there was a much larger amount of connective tissue than elsewhere, which surrounded the muscle bundles or even individual cells, and was much coarser than in the tumor proper. Between the muscle fibers there was a considerable infiltration with lymphocytes and fibroblasts.

The section was not very vascular, and yet there were many more capillaries than are usually seen in tubercles of that size. Especially noteworthy was the fact that well preserved capillaries were frequently found in the very center of the larger neurotic areas. The larger arteries of the myocardium and pericardium had somewhat thickened walls, but little endarteritis. The smaller arteries, especially near the tumor, were more markedly changed; the media was hyperplased to double or three times the normal thickness, and presented marked signs of degeneration; the lumen was frequently almost obliterated by the arterial thickening, though there was no thrombosis.

The picture presented by other sections did not differ materially from the one described. In some places the giant cells were much more numerous and more widely distributed, however, so that they appeared in numbers in nearly every field; also the vascular changes were in general more pronounced. There were more dilated capillaries in the tumor parts, and even the large arteries presented the highest grade of mesarterial thickening, and marked endarteritis as well. The "grayish-white patches" in the left auricular appendix were merely a fibrous thickening of the endocardium; but the pericardium in the same part of the heart showed lesions similar to those in the heart muscle, consisting of a general infiltration and localized nodules of lymphocytes, connective tissue cells, and Langhans' giant cells.

The condition in the kidney was quite analogous to that in the heart. The sections taken through the deeper of the two depressed areas showed numerous isolated foci of cellular infiltration, and one large mass which contained scattered areas of necrosis alternating with collections of cells and with frequent remains of kidney substance—individual cells and fragments of cells, bits of tubules, glomeruli, and larger masses of renal tissue. The cells were almost entirely small lymphocytes. There were practically no epithelioid cells and very few plasma cells. Giant cells on the other hand were remarkably numerous, being scattered over the field almost as they would be in a giant cell sarcoma. The majority of them were clearly of the Langhans' type; but some were irregular in form with an irregular arrangement of the nuclei, and these assumed especially large proportions. Connective tissue cells appeared in comparatively small numbers, and interstitial fibers were present only in the most delicate of strands, which, however, were almost uniformly distributed.

The kidney substance had suffered a marked parenchymatous degeneration in which all parts of the kidney were affected. But the process had advanced further than that. Not only were the convoluted tubules swollen and degenerated, but between them was a large amount of young connective tissue. Similarly, the glomeruli were often overspread with a perfect network of fine connective tissue fibers. All parts of the kidney were exceedingly vascular, including even the necrotic areas. The arterial changes were still more advanced than in the heart. All three of the arterial coats were affected, and the lumen was contracted even to complete obliteration.

The more superficial area near the upper pole of the kidney presented mainly arteriosclerotic changes—substitution of the glomeruli by connective tissue—dense connective tissue bands between the tubules, and marked lymphocytic infiltration. The arteries here were thrombosed in addition to the arteriosclerotic changes, and the capillaries presented the same congestion as elsewhere.

The microscopic changes just described could be caused by only two diseases, tuberculosis or syphilis. To accept the former etiology it would be necessary to assume that the lesions were extremely atypical, whereas the picture corresponds excellently with typical gummata as they have been described elsewhere in the body. The irregular nodular appearance of the lesions macroscopically, the general distribution of epithelioid cells and fibroblasts, the large number of the latter, the presence of capillaries even in necrotic parts, the absence of tubercle bacilli, all speak for gummata. A large number of Langhans' giant cells has been considered a point against syphilis. Baumgarten[1] goes especially far in that direction, but in the very article in which he almost denies the possibility of lesions with Langhans' giant cells being pure gummata he gives the various other differential points between tuberculosis and syphilis, and for all of them the present case might easily represent the type of syphilis.

In this connection it is interesting to note that Van Huellen[2] has recently published a case of sudden death due to heart gumma, in which he lays great stress on the presence in the lesions of enormous numbers of giant cells, some of them of the Langhans type; and Stockmann,[3] after reviewing the entire literature of heart gummata in adults, declares that the presence of giant cells in unquestionable gummata is by no means rare. The heart lesions may be accepted from internal evidence alone as syphilitic; that evidence is strengthened by the absence of any sign of recent tuberculosis elsewhere in the body, and by the unquestionable history of syphilis obtained.

The case, considered as a whole, is perfectly clear. The history gave conclusive evidence of an acquired syphilis and of heart lesion of at least one year's duration. The examination of the heart showed no disease other than syphilis and that in a recent not obsolete form of gummata, which had invaded three of the four heart cavities, reaching their greatest dimensions in the left ventricle, where they formed one huge conglomerate. There is no doubt that this disease of the heart was the cause of the sudden death. Interesting, apart from the wide extent of the gummata, are the large number of Langhans' giant cells and the lesions of the kidney.

COMPARISON WITH OTHER SPECIMENS OF HEART SYPHILIS.

Professor Chiari kindly placed at my disposal three specimens of heart syphilis from the pathologic museum, and of these two appear worthy of a short description. Unfortunately, the catalogue of the museum failed to give the data necessary for a complete report of the autopsies, to say nothing of the clinical aspects of the cases.

The first case (museum No. 811) was a heart markedly enlarged, even for a very heavy person; and this enlargement was due to hypertrophy and dilatation of both left and right ventricles. In the former the dilatation predominated, the wall not exceeding 2 cm. in thickness, whereas the cavity was dilated to approximately 80 cu. cm.

The right ventricle, on the other hand, had less dilatation, but the wall was fully as thick as that of the left side. Unlike the latter, this increase in size was not due to muscular hypertrophy but to the growth of exceedingly numerous small nodules, which had infiltrated every part of the myocardium, including the septum. These did not project into the ventricle like huge knobs, as in the case previously described, but merely gave the endocardium an uneven appearance, like that of a hobnailed liver in advanced cirrhosis. The pulmonary and tricuspid valves, as also the right auricle, were normal. The left ventricle was free from the new growth in the greater part of its extent, only just below the attachment of the aortic valve there was one small nodule. The valve itself was slightly thickened, but the intima of the small piece of aorta attached looked perfectly smooth. The right auricle, including the auriculoventricular ring, was the seat of large masses of tissue, which here did not form distinct nodules, but had infiltrated the muscle in a more uniform manner.

Various parts of the heart were examined microscopically by the same methods as mentioned above.[4] The museum diagnosis of "syphilis cordis" was amply corroborated. Large areas of the tumor masses consisted of old connective tissue, but scattered here and there were numerous foci of cellular infiltration.

Of recent necrosis there was little to be seen, though there were places where the connective tissue seemed to be organizing at the site of former necrosis. There was also a small amount of calcification. The cellular foci were irregular in outline, and presented no definite arrangement of the cells, which were almost all small lymphocytes. There were no epithelioid or giant cells. These foci were usually grouped around a small artery. In addition to the circumscribed, there were many diffuse infiltrations of lymphocytes among the connective tissue and muscle fibers. Unlike the former case, there were bits of muscle tissue scattered throughout the new growth. The blood vessels presented advanced changes, both hyperplastic and degenerative, in which all three coats took part.

[3] Stockmann, W.: "Ueber Gummiknoten im Herzfleische bei Erwachsenen." Wiesbaden. 1904.

[4] All three of the museum specimens were preserved in alcohol; and although two of them had been in that fluid over thirty-five years, they yet possessed staining powers almost as good as those of fresh objects; such differential stains as the Van Gieson or Weigert's elastic stain giving perfect results.

The second heart (museum No. 2,817, a case from the Invalidenspital in Prague) was still larger, measuring 15 by 12 by 10 cm. The greater part of the heart was taken up by the enormously dilated and somewhat hypertrophied left ventricle. The right ventricle was only moderately enlarged; the auricles were of normal size, and presented no abnormalities other than an open foramen ovale. In the upper half of the left ventricle the myocardium was infiltrated by a more or less uniformly distributed, firm, smooth, new growth. The surface of the endocardium was even, not nodular as in the other cases. The greater part of the right ventricle was of a similar appearance. Furthermore, the upper part of the septum ventriculorum presented a deep, circumscribed depression in the right ventricle—an *aneurysma partiale chronicum*. The ascending aorta was the seat of advanced chronic aortitis of the type of syphilitic aortitis.

Microscopically, the tumor masses consisted entirely of dense, round-celled infiltration, interspersed with a considerable amount of connective tissue, mainly in fine fibers with comparatively few cells. There was almost no necrosis present. In addition to the general infiltration, there were very many circumscribed areas of still denser lymphocytes without any connective tissue. These foci occasionally contained one or more Langhans giant cells and a few epithelioid cells, but the latter never had any special arrangement. The foci were usually grouped near one of the very numerous small arteries. The giant cells also occurred in the areas of general infiltration. The heart muscle was somewhat degenerated, and the arteries all presented an advanced panarteritis.

In both of these cases the search for tubercle bacilli proved fruitless. The third case of syphilis of the heart which was examined (museum No. 3,289) contained no circumscribed gummata, merely a fibrous myocarditis, so that any further description of it may be omitted.

Syphilis of the heart with gumma formation is not exceedingly rare. Stockmann,[3] working in Professor Benda's pathologic laboratory in Berlin, was able in 1904 to collect 84 reported cases of circumscribed gummata, of which, however, he rejected several entirely and accepted as surely gummata 56. Since then at least 5 more cases have been published (Würth,[5] Handford,[6] Romanow,[7], Takeya,[8] Van Huellen.[2])

It may not be out of place to summarize briefly some of Stockmann's facts and conclusions. He found that in the majority of cases several or numerous gummata were present, only rarely a single gumma and that generally a conglomerate. All parts of the heart have been affected; the left ventricle by far the oftenest, the auricles seldom. The blood vessels regularly are diseased. From the clinical point of view he had to draw his conclusions cautiously because the clinical picture was seldom complete. Thus, only in 15 cases was the time of infection given, and this occurred from 3 to 30 years before death, and averaged 11 years. As corollary to that, the most deaths occurred between the ages of 30 and 40. The important question of how soon after infection the gummata appear, was, of course, exceedingly difficult to decide, since very few authors stated when the first symptoms appeared. This was doubtless due a great deal to the fact "that the patients felt perfectly well up to the time of their sudden death." A characteristic clinical course can not be set up. The commonest symptoms are tachycardia, arrhythmia and dyspnea. Other symptoms that appear frequently are pain over the heart region, a feeling of anxiety as in angina, palpitation, asthma, headache, vertigo and fainting spells. The physical examination usually reveals an enlarged heart, accentuated second pulmonic sound, the signs of a valvular lesion, and a small, irregular, rapid pulse, or sometimes a slow pulse.

Of the 49 cases in which the cause of death was reported, 15 died suddenly without any previous symptoms, and in 10 more the death was unexpected, although the patients had had signs of heart trouble. In 15 cases, the disease progressed slowly, and in 9 the death was attributable to another cause. Of 16 cases in which the left ventricle and septum were affected, 12 patients died suddenly; in 3 when the right ventricle alone was the seat of the disease, death came slowly.

The inability to obtain any history in so many of the published cases seemed to justify reporting the present one, aside from its interest as a widespread disease of the heart without clinical manifestations.

GONORRHEA IN THE FEMALE.

ITS DIAGNOSIS, FREQUENCY AND INFLUENCE IN THE PRODUCTION OF STERILITY AND OF GRAVE LESIONS OF THE PELVIC ORGANS.*

L. H. DUNNING, M.D.
INDIANAPOLIS.

It is my purpose to consider the question of gonorrhea in the adult woman and as it affects her reproductive organs only. My attention was especially directed to the subject in reading the series of papers read before the Section of Hygiene and Sanitary Science at the last session of this Association and by reading other contributions to the literature of the subject, notably the book by Morrow on "Social Diseases and Marriage," and the report of the committee of this Association, on "Prophylaxis of Venereal Diseases."

In these writings, the authors speak with such assurance regarding the frequency of gonorrhea and its disastrous effects, that one inexperienced in the matter would be led to the conclusion that the diagnosis of the disease is easily accomplished and that the disastrous effects are inevitable. This is in a measure true regarding the diagnosis in acute cases in which an opportunity is given for adequate examination. It is quite different in the chronic and subacute cases. After the disease has been in progress a considerable time the gonococcus of Neisser has disappeared or has become sequestered so that frequently any examination known at the present time will be inadequate to detect its presence, and without the finding of the gonococcus in the secretions or tissues of the patient, the diagnosis of the disease must be uncertain. For practical purposes, it is sufficient as a rule to accept the statement of the husband or lover that he was affected by gonorrhea at the time of cohabitation, if such act is followed by inflammatory lesions of the urethra, vulva, vagina or cervix uteri and in a woman heretofore healthy.

The history of the case, too, will afford some corroboratory evidence in cases, for instance, of young married women, previously healthy, who immediately after marriage develop a purulent urethritis, vulvitis or vaginitis.

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

The difficulties then in making a diagnosis in the chronic and subacute cases are the infrequency in which we are able to demonstrate the presence of the gonococcus, the inability to obtain a satisfacory history of the cases and the fact that gonorrheal inflammation presents no pathognomonic signs, symptoms or course. The specific and nonspecific inflammatory lesions of these organs present exactly similar clinical pictures. Knowing these facts I was startled by some of the statements contained in the articles above referred to, especially the following, which I quote from the "Report of the Committee on Prophylaxis of Venereal Diseases," viz: "In women through most serious involvement of the pelvic genital organs and their adnexa destroying fecundity and giving rise to mutilating operations, 80 per cent. of all deaths from diseases of women are due to gonorrhea. Fifty per cent. of all involuntarily childless marriages are caused by gonorrhea of the female organs of generation, of which 45 per cent. are due to marital infection by men."

These statements were greatly at variance with my opinions formed by many years' practice as a family physician, and later as a gynecologist to a large charity hospital and two free dispensaries and in private practice as a gynecologist. I felt that I was greatly in error in my conclusions or else that the authors of this report had made statements concerning a subject of which they had not full knowledge.

It was for the purpose of setting myself right that I began the study which has resulted in the writing of this paper, and now after a considerable time spent in hard labor, I find myself in the position of every man who has undertaken the study of the subject of gonorrhea in the female, viz., that I have accomplished but little because of the difficulties in the way of positive diagnosis in many cases, and because of the lack of collective investigation.

Morrow in writing on one phase of this subject very truly says: "No one knows better than the writer of this paper, that the proportion of sterile marriages due to gonorrhea is an unknown and unknowable quantity, that it is impossible to present figures that aim at even approximate accuracy."

During the year beginning, June 1, 1904, and ending May 31, 1905, I examined in my office 358 new cases of women seen by me for the first time, and having disease of the genital organs. In each case, a careful record was made of the history, present condition and findings. In this number I found but three cases of acute gonorrhea. Of these, two were married women, and one was an unmarried woman. My assistant made numerous examinations of cover-glass smears of secretions taken from the vagina and cervix and from the urethra, also in all cases of discharge, and in not a single instance except those mentioned above were they able to find the gonococcus of Neisser. The Gram method of staining was employed. The culture method was not used. There were several cases in which I strongly suspected gonorrhea and took every precaution to prevent a spread of the disease to other patients. Who can tell how many cases of gonorrhea there were in the number? I confess I can not. Possibly, too, it as as Veit says, "The vast majority of first cases of gonorrheal infection in the female disappears spontaneously, leaving behind but few traces of the disease."

Certain it is that it is will nigh impossible to obtain the bacteriologic proof of the presence of gonorrhea in the female and no other evidence is accepted as conclusive. Even in some of the severe cases, the patients recover completely so far as the physical examination can determine. The following case is cited as an illustration of this fact:

Patient.—Mrs. A. consulted me Oct. 3, 1902, for the purpose of ascertaining why she did not become pregnant. She was a fine looking, well-nourished woman, 34 years of age. She had enjoyed almost perfect health for several years. Her only suffering was at the menstrual period, which recurred regularly every thirty-four days. The flow was moderate, lasting four days, and was very painful at the commencement.

Examination.—A physical examination failed to show any evident signs of disease of the reproductive organs. There was no endometritis and no displacement of the organs. They were of normal size and not unduly sensitive to pressure; in short, the uterus and adnexa, so far as I could determine, were perfectly healthy. She stated that her health was all she could desire, and that she came to me only because she thought I might be able to advise her in such a way that she might bear a child.

Remarks.—Nine years previous to this examination and soon after her marriage, I treated her for gonorrhea contracted from her husband. Her case was a severe one, and I thought was attended by the development of a pus tube. After a few months' treatment the inflammation of the bladder, uterus and adnexa disappeared, so that at the end of a year all traces of the infective lesion had disappeared. Now she is sterile and wants children. I informed her I was unable to give a reason for her sterility. Her husband may have been in fault or there may have been in her case a closure of the lumen of the Fallopian tubes. Which it was I am unable to say.

How many cases similar to this one there are in the practice of each one of us no one can tell. The early history of this case, however, if drawn from her might have enabled her physician to suspect that she had been the victim of gonorrhea. In order that light may be thrown on this subject, the recorded history of each case should give a more or less detailed account of a very serious illness since puberty and an especial account of any illness the patient may have had during the first few months of married life, the point especially noted being any deviation from normal in respect to urethral or bladder inflammation, vulvitis, vaginitis, leucorrheal discharges, and illness ascribed to disease of the adnexa.

I have made a careful study of my records of office patients to ascertain, if possible, what light, if any, they might furnish relative to the influence of gonorrhea on primary sterility. These records show that of 548 consecutive cases of women who had been married five years or more, there were 59, or 10 per cent., who had never been pregnant.

Of this number there were 12, or 21 per cent., who according to their own statements, used active means to prevent pregnancy. There were 6, or 10 per cent., of cases of gonorrhea discovered either by means of bacteriologic examination or on admission of the husband. Of lesions inducing sterility there were 6 cases of pronounced anteflexion of the uterus; 11 of fibroid tumor of the uterus; 5 of undeveloped uterus; 4 of retroversion and retroflexion, thus making 27, or 45 per cent., of diseases producing sterility that could not in any way be attributed to gonorrhea. Adding to the 45 per cent., 21 per cent. in which active preventive means were employed to prevent conception, and we find 66 per cent. of cases of primary sterility, according to my figures, due to diseases and conditions other than gonorrhea; but 10 per cent. could positively be ascribed to gonorrhea. The lesions found in the remaining cases were as follows: Three cases of ovarian cysts; two of cancer of the breast; two of tuberculous peritonitis; one of prolapsus of the uterus and adnexa; three of carcinoma of the cervix uteri; one of endometritis alone; one of chronic ovaritis, and two in which no lesion was discovered. It is true that in but few of these cases was a bacteriologic examination made to determine the presence or absence of the gonococcus, nor indeed, was it needed, for no one would think of attributing sterility in a case of marked anteflexion to gonorrhea, or in one of fibroid tumor of the uterus to gonorrhea, or in one of an undeveloped uterus to that infectious disease.

Again my records show that in 321 consecutive cases of women who had been married 5 years or more there were 61, or 19 per cent., who had been pregnant but once. To determine the cause of sterility is a difficult task. My belief is that it is most frequently due to a successful effort on the part of the woman, with the sanction of the husband, to prevent impregnation. This is a harsh statement and possibly should not be made without submitting as proof the facts on which it is founded. This I can not do, but I will say that I have listened so often to the statement: "I do not want any more children and will not have them," in answer to my question, does the patient know of any reason she has not borne children since the last one, now 5 or 10 years of age, that I have ceased to put such a question, except in rare instances, and have taken it for granted that the patient has employed means she deems harmless to prevent pregnancy. What must we think of the slogan of Dr. Anna Shaw, "No ballot, no babies." Our excellent President Roosevelt seems to think he knows perfectly well that race suicide is most largely due to the voluntary efforts of the possible patients to avoid large families.

The second great cause of primary sterility as I see it, is found in the errors of development of the reproductive organs of women.

Tait[1] in speaking on infantile uterus and after relating the history of an extreme case, says, "Such an example as this is not common, while on the other hand a slight degree of the want of development of the uterus sufficient to give rise to troublesome menstruation and to be a bar to pregnancy is quite a common condition, so common that I almost think I might say it constitutes almost one-half my private practice in chambers, and a large proportion of my out patient hospital practice consists of cases of such arrest of development. I have a strong and growing belief that the exanthematous lesions of childhood are largely to be charged with this as a result."

In my list it will be noted that of the 59 cases of primary sterility there appeared 16 cases, or 27 per cent. of errors of development of the uterus, viz., 6 cases of anteflexion of the uterus; 5 of infantile uterus, and 4 of retroversion and retroflexion. Cases of marked anteflexion and retroflexion of the uterus in the young must be classed as errors of development. The exact influence of gonorrhea in producing sterility, while it is no doubt great, has not yet been determined.

How great an etiologic factor is gonorrheal infection in the grave pelvic lesions of women?

The result of my study disproves the statements quoted from the report of the association committee at the beginning of this paper, viz., that 80 per cent. of all deaths from pelvic diseases of women are due to gonorrhea. It shows at least that in my private practice and in the only charity hospital in Indianapolis, no such preponderance of grave pelvic lesions are due to gonorrheal infection. Before giving a résumé of my findings it is but proper to state that one of the difficulties entering into a solution of the question under discussion is the marked difference that prevails in different communities and countries relative to the prevalence of any disease. This well-known fact needs no discussion. I think all will concede it. Only collective investigation can bring satisfactory and final conclusions. I present my facts for what they may be found to be worth, not claiming for them conclusiveness.

During the year of 1904, I invaded the peritoneal cavity by operative procedure 167 times. In the patients operated on, 111 operations were done for the relief of diseases of the pelvic organs. These operations are classified as follows: Supravaginal hysterectomy, for fibroid tumors of the uterus and cancer of the uterus, 23 cases; vaginal hysterectomy for cancer of the uterus, procidentia and senile endometritis, 15 cases; salpingo-oöphorectomy for inflammatory lesions (mostly suppurative) of the tubes and ovaries, 30 cases; ventrosuspension, 6 cases; ovariotomy for ovarian cysts, 32 cases; vaginal section for broad ligament phlegmon, 1 case; shortening the round ligaments, Goldspohn's method, 1 case; sarcoma of the uterus, 1 case; herniotomy, 1 case; tubercular peritonitis with involvement of the Fallopian tubes, 3 cases; intra-abdominal shortening round ligaments, 6 cases. Only 30 cases, or 27 per cent., could possibly be attributed to gonorrhea. I attributed but 15, or 13.5 per cent., to gonorrheal infection, for all my experience is in accord with Ashton's,[2] who says, in speaking of salpingitis: "The vast majority of cases that are septic are puerperal in origin and they even exceed in number those due to gonorrhea."

Gonorrheal salpingitis is a serious lesion frequently leading to sterility and chronic invalidism, but not so frequently producing death of the patient as the infections following abortions or confinement. In my 30 cases of salpingo-oöphorectomy a bacteriologic examination was made in suspected cases, viz., in those in which the infection could not clearly be attributed to other causes or in those cases giving a clear history of exposure to gonorrhea; in but 3 of the cases was it possible to demonstrate the presence of the gonococcus. The inability frequently to find the diplococcus in chronic cases of suspected gonorrhea is so common that one soon tires of the hunt. Recently my assistant, Dr. Thurston, examined the secretions from 13 new patients, i. e., patients at first examination in whom there were cervical erosions and endometritis and in 2 of them purulent discharges from the urethra, yet he failed to find the gonococcus in a single instance; and still the histories were such in 3 of the cases as to lead me strongly to suspect the disease. It would be manifestly unjust to classify these as specific cases. There are no pathognomonic signs or symptoms of the disease. Every lesion of the female genitalia found in gonorrhea is also found in the same intensity and running a similar course in perfectly non-specific causes. If, then, we fail to demonstrate the gonococcus of Neisser in the secretions or tissues of the patient and make a diagnosis of gonorrhea we must do it on suspicion, a most unscientific method.

Clark[3] has cogently stated the present status of our knowledge of the inflammatory lesions of the Fallopian tubes, and what he says of this applies with equal force to all other inflammatory lesions of the female pelvic organs. He says: "Without question, the classification of diseases according to their etiology would be preferable on account of their greater scientific accuracy, but so far neither a careful bacteriologic examination nor microscopic sections are sufficient to reveal the primary infecting or exciting agent in a majority of cases."

---

[1] "Diseases of Women and Abdominal Surgery," p. 154.

[2] "Practice of Gynecology," p. 489.

[3] Reed: "Text-Book of Gynecology," p. 488.

As an aid in determining the frequency of gonorrhea in the female in our city, Dr. Paul Martin, superintendent of the Indianapolis City Hospital, at my request, made a brief tabulated report of all cases of women admitted to the hospital during the year of 1904. This hospital is a charity hospital and is the only one in the city into which venereal cases are admitted for treatment.

Dr. Martin tells me that all suspected cases of gonorrhea in both male and female are examined bacteriologically unless the history of the case of infection is clear or confession of the patient is made. The system of records introduced by Dr. Martin and kept on file is very elaborate and for the most part satisfactory, and from these records he compiled the report I have alluded to. The points brought out were the hospital number of the patient, the fact of the existence of acute or chronic gonorrhea, the manner of diagnosis, the results of bacteriologic examinations, and the lesion present.

There were treated in that institution during the year of 1904, 651 female patients.

There were diagnosed, either by bacteriologic examination or by confession of the patient: Acute gonorrheal cases, positive, 25; acute gonorrheal cases, doubtful, 4; chronic gonorrheal cases, positive, 49; chronic gonorrheal cases, doubtful, 9.

Of this number there were those who confessed to having or to having had gonorrhea, positive, 50 cases; doubtful, 3 cases.

Bacteriologic examinations were made with positive results in 29 cases; with negative results in 16 cases; with doubtful results in 3 cases.

It will be seen by this report that there were in all 74 cases in which a positive diagnosis of gonorrhea was made; in other words, 11 per cent. of the women admitted to the hospital at the time of admission had, or had previously had gonorrhea. This is the only hospital in our city, of 200,000 inhabitants, that admits gonorrheal patients, and admission of patients with venereal diseases is denied to none. It will be remembered that there were 49 patients classified as chronic cases, in the majority of which the diagnosis was made by confession and in which at the time there were no positive evidences of the disease. The diagnosis in these cases was based on the confession of the patients, every one of whom was asked on admission if she had ever had gonorrhea and her statement recorded. Of 49 cases recorded as chronic gonorrhea, 37 patients came to be treated for other disease, and of this 37, 4 were pregnant. Some further details of the report are of interest.

There were brought into the hospital either during or immediately after abortion 21 patients, of whom 18 were free from gonorrhea and 3 confessed to having had that disease.

The records show that 24 patients were treated for salpingitis, of which 12 were gonorrheal infections and 12 non-gonorrheal; there were 3 cases of ovaritis, 1 gonorrheal and 2 non-gonorrheal; there were 5 cases of pelvic abscess, 1 gonorrheal and 4 non-gonorrheal; there was 1 case of pelvic septicemia, non-gonorrheal; 3 cases of pelvic peritonitis, 1 gonorrheal, 2 non-gonorrheal and 3 cases of vulvar abscess, 1 gonorrheal, 2 non-gonorrheal. There were, therefore, 16 gonorrheal and 24 non-gonorrheal cases.

To make the list of serious lesions complete, we should include 21 cases of abortion, 18 non-gonorrheal, 3 gonorrheal; 12 cases of fibroid tumors of the uterus, 5 of carcinoma of the reproductive organs and 1 of ovarian cyst. Thus making 79 cases of serious pelvic lesions, of which 19 patients had at the time or had had at some previous time gonorrhea, or 24 per cent. of the patients with grave lesions had gonorrhea.

There were at the hospital during the year 6 deaths from pelvic lesions, distributed as follows: Carcinoma of the uterus (only operative cases were admitted), 3; pyosalpinx, non-gonorrheal, 1; double oöphoritis, non-gonorrheal, 1; puerperal septicemia, 1; total 6.

REPORT OF BOBB'S FREE DISPENSARY.

It should be stated regarding this dispensary that it is a dispensary under the direction of the Medical College of Indiana and each department is presided over by a professor in that department. This dispensary is maintained for teaching purposes and is abundantly supplied with experts and appliances. It maintains a chemical and microscopic clinical laboratory to which are sent by the clinicians specimens of urine, morbid secretions and tissues for examination.

The gynecologic department is presided over by Professors O. G. Pfaff and Chas. E. Ferguson, both of whom are accomplished gynecologists. They report that, while no prostitutes are denied treatment in their clinics, yet few of this class apply, and that they think 10 per cent. is a conservative estimate of the number of prostitutes seen in their departments. Every patient suspected of having gonorrhea, especially if there is a purulent discharge from the uterus, Skene's or Bartholin's glands, is carefully scrutinized and specimens of the genital secretions sent to the laboratory for bacteriologic examination. A fairly good record of all the work done in the dispensary is kept. The card system being used for this purpose.

At my request, Dr. Helen Knabe, a paid assistant in the laboratory, made a careful study of the records and compiled from them the report herewith submitted:

BOBB'S FREE DISPENSARY, JUNE 1, 1904, TO MAY 31, 1905.

Eight hundred and forty-four female patients were treated during the year. They were distributed in the different departments as follows:

(*a*) General medicine (including nervous diseases)	283	
(*b*) Diseases of the eye	171	
(*c*) Gynecology	108	
(*d*) Diseases of children	86	
(*e*) Diseases of ear, nose and throat	84	
(*f*) Dermatology	43	
(*g*) Surgery	36	
(*h*) Gastrointestinal diseases	24	
(*i*) Genito-urinary diseases	9	
Total	844	
Number of cases of gonorrhea in all departments	10	
(*a*) Gynecology	5	
(*b*) Diseases of children (vaginal)	2	
(*c*) Diseases of the eye	2	
(*d*) Genitourinary disease (vaginal)	1	
Total of cases	10	
Classification of gonorrheal cases		
(*a*) Acute cases	2	
(*b*) Chronic cases	3	
Total	5	
Method of diagnosis in gynecologic department:		
(*a*) By bacteriologic examination	3	
(*b*) By confession of patient (one rape)	2	
(*c*) By clinical symptoms alone	none.	
Location of lesion:		
(*a*) External organs	2	one acute. one chronic.
(*b*) Uterus and adnexa	3	uterus—1 chronic. ovaries—1 chronic. Pyosalpinx—1 acute.

Occupation of patients having gonorrhea:

(*a*) Merchant (married)	1
(*b*) Housekeeping (married)	1
(*c*) Works in family (single)	1
(*d*) No occupation (single, probably prostitute)	1
(*e*) No occupation (widow, probably prostitute)	1
Total	5

History of patients in respect to sterility and fecundity:
(*a*) Sterile, 2; one of them married, the other widow at the present time.
(*b*) Children, 1; married, had one child fifteen years ago.
(*c*) Unmarried, no children, 2.

Pregnant since having gonorrhea.......... 0

Grave lesions of pelvic organs in gynecologic cases:

(*a*) Carcinoma	0
(*b*) Uterine tumors (fibroid)	2
(*c*) Salpingitis, chronic	1
(*d*) Pyosalpinx, acute (gonorrheal)	1
(*e*) Suppuration of ovary and tube	1
(*f*) Ovarian tumors	0
(*g*) Ovaritis, non-suppurating	3
(*h*) Pelvic inflammation	1

Slight pelvic lesions of gynecologic cases:

(*a*) Prolapse of ovary	4
(*b*) Prolapse of uterus	1
(*c*) Subinvolution	1
(*d*) Superinvolution	1
(*e*) Lacerated cervix	14
(*f*) Erosion of cervix	8
(*g*) Retroversion	12
(*h*) Retroflexion	1
(*i*) Endometritis (1 gonorrheal)	10
(*k*) Acute vaginitis, nonspecific	2
Acute vaginitis, microscopic ex	2
(*l*) Lacerated perineum	12
(*m*) Vaginal chancroid	1
(*n*) Pinhole os.	1
(*o*) Urethral caruncle	1
(*p*) Cystitis (pronounced)	1
(*q*) Cystocele and rectocele	2

Organs removed before coming to *dispensary*:

(*a*) One ovary removed (6 years ago)	1
(*b*) Both ovaries removed (1 and 2 years ago)	2

(In one case of prolapse of the uterus there was also an amputation of the cervix and perineorrhaphy some two years ago.).

Cases in which no diagnosis was recorded, 21. In most of these there was insufficient history to draw any conclusion as to nature of trouble.

The percentage of prostitutes in gynecologic departments was probably less than 10 per cent.

REMARKS ON REPORT.

It will be seen on study of this report that but 87 gynecologic cases are available for study. This shows 5.7 per cent. of patients of this department were subjects of gonorrhea. While, in the whole dispensary, it appears that in 1.2 per cent. of cases was gonorrhea detected.

The records regarding sterility are of no value. Of the grave pelvic lesions, there were 9 cases, of which 1 was due to gonorrheal infection.

CONCLUSIONS.

1. Acute gonorrhea in the female is easily diagnosed if seen early, when both the smear and culture methods may be employed. In the chronic and subacute cases a positive diagnosis is often impossible. All secondary aids to diagnosis, if necessary, must be considered, such as confession of the patient, sudden onset of inflammatory lesions without other causes.

2. Many cases of gonorrhea in women recover quickly, leaving behind no traces of the disease.

3. Different communities differ in respect to the prevalence of the disease. I submit the following summary of cases which I have collected:

	Number of women treated.	Having gonorrhea.	Percentage.
City Hospital	651	74	11
Bobb's Free Dispensary	844	10	1
Private practice	360	4	1
	1855		

These figures can not be taken as an accurate statement; they are only approximately true.

Probably the City Hospital figures are most nearly accurate, but in considering these figures it must be remembered that probably more than 66.6 per cent. of all cases of gonorrhea at that institution occurred in prostitutes, while the number of this class admitted to the hospital is a much smaller percentage of the whole; how much smaller it is impossible to determine, because few women will voluntarily admit to hospital authorities that they are prostitutes.

In the City Hospital report the number of cases of grave lesions of the pelvic organs was 79, of which 19 were gonorrheal and 60 non-gonorrheal cases, 24 per cent.

In Bobb's Free Dispensary there were 9 cases of grave lesions of the pelvic organs, of which 1 was gonorrheal and 8 non-gonorrheal, 11 per cent.

In private cases there were 111 cases demanding grave operative procedures; 15 were gonorrheal and 96 non-gonorrheal; 13 per cent. of operative cases were gonorrheal.

I did not succeed in finding many important facts bearing on the influence of gonorrhea in producing sterility. In my list of 59 cases of primary sterility, 66 per cent. could fairly be attributed to other causes than gonorrhea and but 10 per cent. attributed to gonorrhea; this seems to indicate that gonorrhea as a causative factor in sterility has been overestimated.

DISCUSSION.

Dr. D. H. Craig, Boston, said that he has given some attention to the question of differentiation between the inflammatory lesions, acute and chronic, of the pelvic organs of women classified as puerperal lesions and those classified as gonorrheal. That distinction is often made, as though they represented two absolutely distinct classes, but he thinks they do not. A series of cases he has been tabulating brings that out clearly, and he related one case to illustrate his meaning. A woman presented herself at his clinic with a subacute pelvic lesion, accompanied by moderate pain and a leucorrheal discharge, in no sense characteristic, and attributed her trouble to getting up too early after her confinement, on about the eighth day. All her trouble dated definitely from within 48 hours after getting up. Having this distinction in view, careful investigation was made by smears and cultures, and Dr. Craig found that her trouble was due entirely to a not far remote gonorrheal infection. Very strict questioning of the woman demonstrated the fact that her getting up after confinement was preceded by 24 hours by sexual relation with her husband, who admitted that he had contracted gonorrhea during his wife's pregnancy. Without careful investigation, this case would have been termed one of postpuerperal inflammatory lesion in the pelvis, and would have been laid to some other infection having nothing at all to do with gonorrhea. Dr. Craig thinks these cases are common. Morrow speaks *particularly* of one child sterility. If any one can tell Dr. Craig how a husband having had gonorrhea previous to marriage could be responsible for one-child sterility, he will be glad to learn, but he can understand how the husband contracts *gonorrhea* during his wife's pregnancy and infects her during the *puerperium*. The question of figuring out the statistics of the influence of gonorrhea in causing sterility is an impossible one to answer. In the first place, as Dr. Dunning said, 12 per cent. of women admit preventing conception, but what percentage of that number are taking this step unnecessarily? Many women prevent conception for years, and when they want children they can not have them. What percentage of these women were sterile originally and what percentage made themselves sterile? The prevalence of gonorrhea in all classes has been overestimated. No one man will ever give us reliable statistics on that point. In order to get statistics worth having we must take the statistics of every man whose word we can believe and of every man whose investigations are correct and from that make composite statistics of the whole subject. One man taking the cases in a certain locality among a certain class of people can not give correct statistics as to the prevalence of gonorrhea.

Dr. A. Goldspohn, Chicago, said that if such statistics as Dr. Dunning mentions have been published they are certainly wrong. Dr. Goldspohn has always had the impression that gonorrhea was not so prevalent as has been frequently stated. He was not in a position to declare the statement untrue, however, because he supposed that he did not get the class of patients in whom gonorrhea is more prevalent, although he has a considerable practice from a dispensary in connection with a postgraduate school where a large proportion of the patients are colored, and among these gonorrhea is very frequent. As has been stated, it will not be possible to determine the exact number of gonorrheal infections. A little assistance can be obtained, however, by considering what class of pathologic lesions are caused by gonorrheal infections and what class of lesions by puerperal infections. The puerperal uterus is a very different structure having been emptied of a child, say, within a week or two, than is the ordinary gonorrheal uterus. The former has a succulent, thin, very soft, friable cervical wall; whereas the gonorrheal uterus almost never occurs in the puerperal state, and has a cervix that is almost like leather in comparison. In the former the blood vessels and lymphatics are wide open during the first few days after labor. Infection does not have to travel to the endometrium and out in a round-about way to get to the peritoneal cavity. It passes directly through the lymphatics in the wall of the cervix, into the cellular tissue at the side of the cervix, between the layers of the broad ligament, and there is cellulitis (parametritis). Peritonitis and salpingitis, if they occur at all, are secondary to this. The resulting abscess, if it forms, sometimes ruptures, but more frequently it is drained into the vagina. These cases run their course with or without our help, and the patient may not have a salpingitis at all. Gonorrheal infection, on the other hand, usually does not occur in the recent puerperal state, but later, when the ordinary condition of the uterus and cervical canal has been attained. Therefore, the gonorrheal infection, if it passes into the peritoneum at all, as a rule, travels through the endometrium and the tube and then to the peritoneum. There is always an endometritis and salpingitis, with more or less peritonitis. In this connection, it is easy to see that the cases of localized pelvic peritonitis which result in adhesion of the tube or ovary are very much more frequent than are the cases which result in adhesion of the uterus itself. This difference in the gross pathology of the two conditions is a guide in determining the probable nature of the infection in the beginning in either case.

Dr. W. O. Henry, Omaha, declared that, while these statistics are not large enough to be conclusive, yet they are a beginning, and it is to be hoped that other gynecologists will follow Dr. Dunnings' example and tabulate their cases. Dr. Henry believes that not over 30 per cent. of these cases are gonorrheal, but in the future he will tabulate all cases after having examined them carefully.

Dr. L. H. Dunning stated that his object in presenting this paper was to call the attention of the profession to the fact that lesions due to other causes are too frequently ascribed to gonorrheal infection. If physicians will investigate this matter carefully, he thinks they will arrive at results different from those previously reported. He wrote the paper partly as a protest against statements which are being quoted continually as scientific facts and which are not facts.

Special Article

IMMUNITY.

CHAPTER XXX.

GLANDERS (FARCY).

Occurrence of the Disease.

Under natural conditions the horse is the chief sufferer from glanders or farcy, the former name being applied to the disease as it occurs in the nose, the latter when in the skin. These names are relics of the time when the two forms of the disease were not recognized as identical processes with a common etiology. In either locality the disease may be acute or chronic, and in the horse about 90 per cent. of the cases are chronic. The ass is occasionally infected, and in this animal as well as in man, an acute general infection (bacillemia) frequently develops, in addition to the cutaneous and nasal lesions which characterize the disease. *Fortunately*, glanders in man is rare. Cows and rats are immune, or nearly so; the sheep, goat and dog have fairly high resistance, although they may be infected artificially; the dog and rabbit are moderately susceptible, and for the guinea-pig and members of the cat family (tiger, lion and leopard), the bacillus is very virulent. Infection of the last named animals has been noted in menageries as the result of feeding them with the meat of a horse which had died of glanders. The acute infection usually is fatal, and complete recovery from the chronic form of the disease is infrequent. Something less than 50 per cent. of the chronic infections in man terminate in recovery.

Bacillus Mallei.

The specific microbe, *Bacillus mallei*, discovered in 1882 by Loeffler and Schütz, is an anaërobic organism which has approximately the morphology and size of the tubercle bacillus, but lacks the acid-fast property of the latter. It stains with anilin dyes, especially carbol fuchsin, but not with Gram's method. With weak staining it shows a granular structure. It grows well on ordinary culture media, showing a characteristic appearance on potato. In favorable media it may produce threads, while under more favorable conditions coccus-like forms are seen. The optimum temperature for growth is from 30 to 40 C.

Resistance and Endotoxin.

The bacillus is only moderately susceptible to sunlight, by which it is killed in about twenty-four hours. It withstands freezing, lives for two to three weeks in a dried condition at room temperature, and is killed by a temperature of from 56 to 60 C. in from ten minutes to one and one-half hours, depending on the amount and character of the medium in which it lies. Its resistance to the ordinary disinfectants (corrosive sublimate, carbolic acid, etc.), is not high. Milk of lime and solutions of calcium chlorid are suitable for the disinfection of stalls. In culture media the organism secretes no soluble toxin, but it contains an endotoxin which probably is one of the constituents in the various preparations of mallein.

Preparation of Mallein.

The method by which the mallein of Roux and Nocard is prepared is identical with that used in the preparation of the old tuberculin. A virulent strain of the glanders bacillus is allowed to grow for some time (from two weeks to two or three months) in bouillon which contains from 4 to 5 per cent. of glycerin, the culture is then sterilized by heat and the bacteria removed by filtration. The toxin is not destroyed by high temperatures. Other preparations, also called mallein, are made by extracting ground up bacilli with a solution of glycerin and water (Helman, Kalning), or with water alone (Kalning and others); by killing a liquid culture of the bacillus (Bromberg); or by precipitating bouillon filtrates with absolute alcohol (de Schweinitz and Kilbourne), or with ammonium sulphate or magnesium sulphate. The dry powders "morvin" and "dried mallein" are prepared by one or another of these precipitation methods.

Distribution of Bacilli and Infection Atria.

Glanders bacilli are found only in the tissues and secretions of diseased animals, and the nasal discharges of the latter are the chief means of contaminating feed, water and stables through which the disease usually is carried to other animals. The glanders bacillus does not readily penetrate the intact skin and mucous membranes, although occasionally it may gain entrance through the hair follicles or sweat ducts. In the presence of even slight defects in these surfaces, as those caused in the mouth or nostrils of horses by hay or other food, infection readily occurs. According to Nocard, invasion takes place commonly through the gastrointestinal tract following the ingestion of infected feed or water. Although involvement of the intestines and adjacent tissues frequently results, the organisms may become generalized, causing the disease in the nose, skin or other organs, without the establishment of foci in the intestines.

In man infection occurs chiefly through abrasions in the skin, and perhaps also through the nose, to which the bacilli have been carried by soiled fingers or other means. Several cases of acute glanders, ending fatally, have occurred in laboratory workers as the result of accidental inoculation. There appears to be little danger to man in eating the meat of horses in which the disease was localized, provided the meat has been well cooked. Such meat was fed to soldiers in one instance with no ill results.

Tissue Reactions.

Variations in the course of the disease and in the intensity of the pathologic changes in different cases probably depend on variations in the resistance of the host and in the virulence of the parasite. In acute general infections in man, following an incubation period of from two to five days, during which the point of inoculation becomes violently inflamed, a severe febrile condition develops, which is accompanied by general pains, swollen joints and a macular eruption. In a short time nodules and indurated cords, made up of a leucocytic exudate, edematous fluid and proliferating connective tissue cells, form in the subcutaneous lymphatic channels, and mark the progress of the infection toward the lymph glands. The nodules, and also the cords, commonly undergo softening, and abscesses form and rupture through the skin. Nodules similar to those in the skin develop in various organs of the body; in the nose they break down and constitute ulcers. In chronic infections the lesions are of the same nature, although they evolve more slowly and tend to remain limited to particular regions. Nasal, pharyngeal, tracheal or pulmonary glanders are forms of the disease which are encountered in the horse. Connective tissue development is more marked in chronic than in acute glanders, although the peculiar liquefaction, suppuration and ulceration of the lesions occurs in the former as well as in the latter. Moderate leucocytosis is found in the blood.

Protective Processes.

The nature of the pathologic changes found in glanders, the frequent chronic and the progressive course of the disease, and the fact that infection does not confer distinct immunity, are conditions which ally glanders very closely to tuberculosis, pseudotuberculosis and leprosy. The essential lesion is the "infectious granuloma," and it is probable that the new connective tissue which is formed is to no small extent a factor in limiting the extension of the infection. Nodules of glanders frequently are isolated by the surrounding reaction, the centers caseate and the contents eventually are discharged through the skin; cicatrization and healing in many lesions follow evacuation. Phagocytosis of the bacilli by the epithelioid cells and leucocytes in the nodules is said to be rather extensive. According to Nocard, there is no such thing as an acquired immunity to glanders; chronic glanders may at any time become acute. The cause of the natural immunity of cattle and some other animals seems not to have been determined.

Serum Therapy and Use of Mallein.

Treatment of glanders with immune serums has not been successful. Such treatment has been attempted with serum prepared by immunization with mallein (Semmer), and with the serum of diseased animals (Hell and Toeper). The value of mallein in the diagnosis of glanders or farcy is similar to that of tuberculin in tuberculosis. Although it causes a rise in the temperature of normal animals when given in considerable doses, the reaction produced in infected animals is so much more intense, and occurs with so much smaller doses, that it is generally considered as specific in nature. Some doubt, however, has been thrown on the specificity of the reaction from the facts reported by various observers that toxic substances from other organisms, as tuberculin and other preparations from the pneumobacillus of Friedlander, *Bacillus pyocyaneus*, etc., cause similar phenomena in animals suffering from glanders. Wladimiroff asserts, however, that the reactions caused by these substances differ from that of mallein.

For diagnosis a dose must be used which causes no reaction in a normal animal, and this varies with different preparations. The typical reaction has two essential components: 1, A rise in temperature which begins in from six to twelve hours after the injection, reaches its maximum (from 40 to 42 C.) in from six to eight hours later, where it remains for a few hours, then gradually sinks, only to recur on the second day; 2, an edematous and inflammatory tumor at the point of injection, which begins in from six to eight hours, and runs its course in from three to eight days, ending in resorption (Wladimiroff). Veterinarians generally agree that mallein is a valuable diagnostic agent. Mallein also has been used in the treatment of glanders, but with rather doubtful results.

Bacteriologic diagnosis is accomplished by cultivating the bacilli from the abscess or secretions and testing the virulence of the culture by animal experiments (guinea-pig).

Agglutination.

Normal horse serum agglutinates the glanders bacillus in dilutions of from 1/200 to 1/700, that of the diseased animal in a strength of from 1/1600 to 1/2000. In some instances, however, infection causes no increase in the agglutinating power of the serum. Agglutinins are said to be formed more readily in man than in animals.

Clinical Reports

A CASE OF ACROMEGALY.

D'ORSAY HECHT, M.D.
Instructor in Neurology and Chief of the Neurologic Clinic, Northwestern University Medical School; Associate-Attending Neurologist to the Cook County Institutions, Dunning, Ill.
CHICAGO.

Patient.—The young woman whose case is herewith reported has been under the care of my colleague, Dr. Ludwig Simon, for several weeks, and I acknowledge my indebtedness to him for the privilege of citation.

Family History.—The patient is of Scotch-English descent, was born in Cambridge, England, is 24 years old, single, and at the present time a governess by occupation.

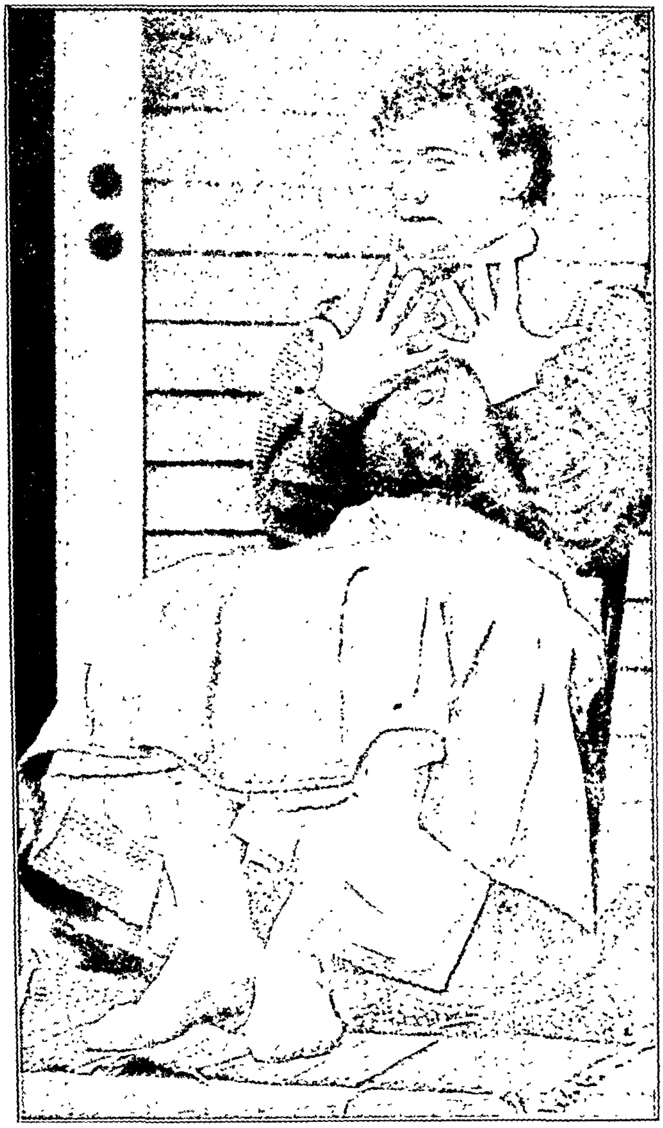
It is interesting to note that Prof. Clifford Albutt diagnosed a carcinoma of the bowel in the paternal grandfather of the patient; a carcinoma of the larynx in an aunt on the maternal side, and an uncle on the maternal side is now afflicted with carcinoma of the bladder. This familial tendency to malignant neoplasms made the patient feel that, perhaps, her headaches and general enlargement were due to a similar growth. Her father, mother, one brother and two sisters are all living and well, though none of them could be called robust. She is certain that no relatives were ever afflicted with a disease answering the description of acromegaly.

Previous History.—The patient seems to have had a full complement of illnesses in the past. She recounts attacks of measles, chickenpox, bronchitis, scarlet fever, quinsy, sore throat, rheumatic fever, brain fever, and, lastly, typhoid fever four years ago. Her menses were established at 11 years of age, and the periods have been uniformly painful. Since her typhoid they have been more profuse, except for an interval of four months, from September, 1903, to January, 1904, when the flow remained away altogether.

Chief interest attaches to her headaches, from which she has been suffering since early childhood. To her knowledge they have never been absent, and when a child at play she had to be very careful of herself for fear of precipitating them. She experienced them always in the form of a right hemicrania, coming on at almost any time of the day, but oftenest late in the afternoon and lasting from one to three days, sometimes attended with nosebleed, but more often with severe vomiting. They came on at regular intervals of two weeks and were called "bilious attacks," because of associated vomiting, which gave her prompt relief. So severe have they been at times that bed rest became imperative. The wearing of glasses has in no way improved these headaches. Since her attack of typhoid and coincident with the progress of her present trouble the cephalalgia is almost of daily occurrence, vesperal in type, of increasing severity, boring and pulling in character, attended with considerable nausea, but no vomiting, and associated at times with a notable puffiness of the fingers and hands, which recedes with the termination of the ache. A younger sister is the only one of her remote or immediate relatives somewhat similarly afflicted.

A little more than four years ago the patient pa a prolonged mental storm as the result of opposition to an issue which greatly concerned her future happiness. In the wake of this infelicity there followed nervous prostration and a series of hysterical attacks, one of which eventuated in a "stupor" that lasted several days. Closely following came an illness of typhoid fever, from which, she thinks, she never fully recovered. Physically she always regarded herself as small boned and small featured. It is a family trait, she states, to be dainty and petite. There is no history of trauma. Personal habits are good. The appetite is fair. Of late there has been much drowsiness, but no refreshing sleep.

Present History.—(Subjective Complaints.) During the convalescence from typhoid, the patient noticed that she could not get into the clothes that had formerly fit her well. She was enough larger in the trunk not to be able to wear them. In answer to an inquiry as to the mode of onset and succession of the various enlargements, she states, "I think the features of my face altered first, but then I seemed to get big gradually all over. *My growth must have been rapid, for a cousin who had not seen me for a year, on her return, failed to recognize me* even in the surroundings of my own home and family." The voice has undergone a notable change of pitch since her attack of typhoid. In her church choir she always sang from soprano scores, but for the past three years the range has been lowered to alto and the voice become harsh. There has been much general malaise, backache and easy fatigue. Added to debility, there is excessive perspiration, and the skin has taken on a somewhat darker and more sallow complexion. She is suffering from violent headaches.



Acromegaly. Photograph taken in June, 1905.

Status Præsens.—Physical examination reveals the following: A woman of good stature, erect, appearing fairly well nourished, but presenting a very flabby musculature.

The trunk: The face is oval, elongated from the nose to the chin and disproportionately wide across the brow. The nose, not quite straight, is conspicuously long and the soft parts are unusually fleshy. The lips are larger and thicker than normal. The tongue, on protrusion, is broad and beefy, with its upper surface irregular and deeply furrowed. The lower jaw is considerably longer than normal, but the teeth are set closely together; there are no abnormal dental interspaces. The cranial bones may be somewhat enlarged, but the head does not impress one as being extraordinarily affected. The neck is short and measures 14¼ inches in circumference. Before the attack of typhoid she could wear a number 13 linen collar, and now she requires a large number fourteen. At the juncture of the sternum with the first two or three ribs there is an undue anterior bulging of the broadened thickened bony structure, and I believe that the area of pyramidal dullness noted over this region by Erb in some of his cases can be elicited here. The ribs feel thick.

The limbs: The hands are markedly enlarged in the broad diameter, measuring 8¼ inches; the fingers appear short, thick and stubby, but not clubbed; the normal "tapering" is altogether absent. The thenar and hypothenar eminences are prominent, but soft and flabby. The wrists measure 7 inches in circumference. Before her illness she wore a 5¼ glove and now requires a 6¾, which is a snug fit.

The legs show marked outward bowing and thickening of the shaft of the tibia. The foot is wide, broad and flat and its greatest length from ankle to tip of great toe measures about 10 inches. The great toe is relatively much larger and broader than the others. The ankle is also larger. Formerly she wore a No. 4 shoe; now she requires a No. 6.

The Integument: The skin is of a somewhat dirty yellowish sallow hue, oily and sweaty. The hands feel soft, somewhat pudgy and cool. In the region of the left breast there is a small hairy mole. The breasts are soft, flabby and not very large, but the nipples are broad-tipped and coarse. The hair, besides having become some shades darker, has grown coarse in quality and excessive in quantity. The suprapubic and labial growth is thick, coarse and shaggy, and there is an unusual amount distributed over the limbs, abdomen, back and forearms, which according to the patient's statement has appeared only since the inception of the present trouble.

The Eyes: For the special eye findings I am greatly indebted to Dr. Albert Hale, whose report I insert in full: "The condition of the eyes as I found them in your acromegaly case is as follows: Has worn lenses for ten years. Always been myopic. Her last lenses (from England) were of —4.0Ds., with an astigmatism of 1.50Ds. in each eye. I find that her myopia has probably increased about two diopters, for vision of 6/6 is obtained by the following:

R. O.D. —5.75 Ds. —2.0 Dc. 155 ax.
O.S. —5.75 Ds. —2.0 Dc. 10 ax.

"In examining the eyes themselves, there is found this unusual condition: The pupils are small and unaffected by light or accommodation—symmetrically—but this can not be dependent on a central nervous lesion, because even by using the strongest mydriatic no decided effect on the iris can be produced, the dilation amounting at most to only a millimeter. There is no history of iritis given, and, even if there were, an iritis involving each iris so symmetrically would be extraordinarily rare. I can not find a cause in any other local area to account for it. The fundus shows no peculiarity unconnected with a myopia of this degree. *But the smallness of the pupils* does not admit of such a careful examination as this report should require."

Internal Organs: The nervous system reveals nothing abnormal except the headache already referred to. There is no vertigo. There is no cranial or peripheral nerve involvement. The knee jerks are very brisk. The heart is normal; pulse, 80, full, and of good tension. The urine is negative. A vaginal examination was not made.

Treatment.—The therapy has consisted chiefly in the administration of pituitary extract in tablet form. She has been taking three-grain tablets three times a day, alternating with palliatives for her headaches and general tonics for the malaise. It has seemed to me that the taking of pituitary extract intensified the headaches and a discontinuance of the drug has marked several periods of improvement.

Since this is merely a case report, the pathogenesis, differential diagnosis and therapy are not discussed.

A UNILATERAL PARADOXICAL PULSE.

ALBION WALTER HEWLETT, B.S., M.D.
Instructor in Clinical Medicine at the Cooper Medical College.
SAN FRANCISCO.

Patient.—L. A., aged 17. Family and past history were negative.

History.—Beginning in March, 1903, the patient was confined to bed for three months owing to a fever that was supposed to be typhoid, with relapse. During this illness he had very little cough or headache, but toward its termination he experienced severe pain in the left side, which lasted about a week and was made worse by cough and by deep inspiration. A week later he noticed, for the first time, that the left side of his chest was smaller than the right. He believes that this change in his chest took place overnight, and he is very certain that it had not existed before his illness. Since this fever he has been troubled more or less with weakness and with dyspnea on exertion. He has at present no edema, cough, or pain in the side.

Examination.—This shows a fairly well-developed boy; his color is good, and he is inclined to dyspnea and cyanosis on exertion. Examination of abdominal organs, urine, reflexes, etc., was negative.

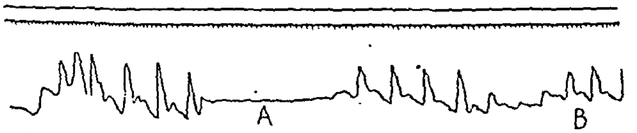

Fig. 1.—Sphygmographic tracing from right radial artery showing effect of respiration. A. Deep inspiration. B. Inspiration.

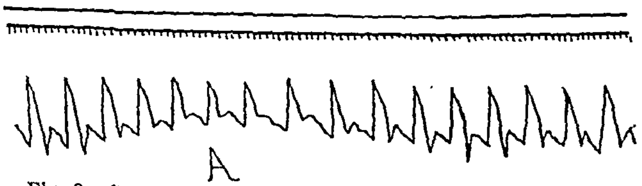

Fig. 2.—Sphygmographic tracing from left radial artery showing effects of respiration. A. Deep inspiration.

Lungs: On inspecting the chest the left side is seen to be much smaller than the right in all its diameters. The left shoulder hangs low, and the left scapula is prominent. The circumference of the right side at the nipple level is 44 cm. on expiration and 46 cm. on inspiration. That of the left side is 36.5 cm. and does not change on respiration. There is a scoliosis to the right in the dorsal region and to the left in the lumbar region. The upper left chest is tympanitically resonant in front as far down as the second intercostal space. It begins here to become dull, and this dullness gradually changes into absolute flatness at the fourth intercostal space. Below this in front and over the whole back the percussion note is flat. The tactile fremitus is increased over the area of resonance, but is diminished over the dullness and flatness. The breath sounds over the upper left front are of the bronchial type; over the upper left back they are distant bronchial. Going down the chest, they become fainter and fainter and are completely absent over the base behind. No râles are heard. The signs in the right chest are such as one might expect over a lung that is doing the work of two.

Heart: The point of maximum cardiac impulse is situated in the fourth intercostal space 7.5 cm. from the median line. The area of cardiac dullness is enlarged somewhat to the right and upward. There is a slight systolic heaving over the whole of the precordium. There is no retraction at the apex and no Broadbent sign. In the second intercostal space just to the left of the sternum a distinct late systolic pulsation is visible which is caused apparently by the movements of the pulmonary artery that has been uncovered by the retraction of the edge of the left lung. The pulmonary second sound is very much accentuated also owing, in great measure, to this retraction of the lung. No murmurs are heard.

Pulses: Under ordinary circumstances the two pulses are of nearly the same size and character. The systolic pressure in each brachial is 116 mm. of mercury (Riva-Rocci, 5-inch cuff). If the patient stands and takes a somewhat deeper inspiration than usual, the right radial pulse becomes small, and if a still deeper breath be taken it disappears entirely (Fig. 1), remaining absent as long as the deep breath is held. Under these circumstances, the brachial and axillary pulses also disappear, but the subclavian can be felt above the clavicle. If the right shoulder be passively elevated during the deep inspiration, the radial pulse may become somewhat smaller, but it does not entirely disappear. The effect of the position of the shoulder is illustrated in another way. If the patient maintains a position of deep inspiration, the radial pulse can be made alternately to appear and to disappear merely by raising and lowering the shoulder. The venous blood flow is not noticeably affected by these maneuvers. Deep respiration does not affect the left radial pulse to any greater degree than is normal (Fig. 2).

Remarks.—The retraction and immobility of this patient's left chest apparently depends on extensively thickened pleuritic adhesions, which have obliterated the greater part of the pleural cavity and have led to retraction of the left lung. The disappearance of the right radial pulse on deep inspiration is evidently due to a mechanical cause lying somewhere between the second portion of the subclavian and the upper axillary artery. This cause is active only when the shoulder is hanging low. Two possible explanations of this unilateral paradoxical pulse have suggested themselves to me. First, there may be a compression of the subclavian artery between the clavicle and some underlying structure such as the first rib. The extreme movements of the right chest caused by lack of function in the left would lift the artery unusually high during inspiration so that it could be more easily compressed by a low clavicle. The other possibility is that the artery may be so bound down by adhesions within the chest cavity that it is kinked over the first rib when this is raised during deep inspiration. Elevating the shoulder might prevent such a kinking by lifting the artery off the rib.

This is not the place to discuss the various forms of the paradoxical pulse nor to go into the various causes that may give rise to this symptom. I have been able to find but very few instances of a unilateral pulsus paradoxus recorded in the literature. In Gerhardt's two cases[1] the unilateral disappearance of certain of the pulsations appeared to be due to a localized arteriosclerotic narrowing of the lumen of the corresponding artery, as was demonstrated in one of his cases by an examination after death. Harris[2] has also reported a unilateral pulsus paradoxus in a patient who had a mediastinopericarditis. He believes that the adhesions affected the left subclavian to a greater extent than they did the innominate, but he was unable definitely to prove this at autopsy.

Causes of Failure.—Some men fail through their overweening confidence or insufferable conceit. The very first thing a student should do is to gauge properly his abilities. He should never excuse his own mistakes. He can not hope to succeed without a thorough mastery of the technic of his profession. He should never place confidence in unadulterated luck. He should recognize early the advantages of a cool head and a clear eye, and learn to practice the old-fashioned virtues of sustained effort and steady industry, otherwise known as patience and grit. Spasmodic study and investigation are worse than nothing, as they cultivate an unscientific mental attitude. Failure through "dry rot" is of itself compensatory and but simple justice.—*Kansas City Med. Index-Lancet.*

THE ESSENTIALS IN STATE SUPERVISION OF INSANE HOSPITALS.

At the recent meeting in Portland of the National Conference of Charities and Correction, the report[1] of the committee on state supervision and administration gave a cheering instance of the more enlightened and scientific view of the treatment of the insane which the public is slowly acquiring. The report reminds us that, at a conservative estimate, the actual yearly increase in the number of insane persons in public institutions in the United States is now at least 5,000, and that the total number cared for by the states has already reached 150,000. Such figures may well cause popular alarm. Whether insanity is relatively increasing or not is still a moot question, but the facts as to the actual increase of the number of insane patients maintained by the states can not be overlooked. In view of these facts the report very properly points out that the neglect of preventive effort in this field is no less than foolhardy. "It is as if a city were to abandon vaccination and content itself with an admirable isolation hospital in which to treat all discovered cases of smallpox."

The report urges as the primary essential of preventive measures, better facilities for the training in psychiatry of medical students, a point which we have emphasized so often in these columns that it is unnecessary to dwell on it here. It describes at length the university hospitals for the insane in Germany, dwelling especially on the admirable care thus secured for the acute patient, as well as on the opportunity for clinical study afforded to the student, and emphasizing a fact not always realized by the public, namely, that nowhere are patients so sure of good medical care as in institutions where teaching is done in the wards. "The university clinic in psychiatry, at its best, is a small, suitably equipped hospital for the insane, serving also for the purpose of a hospital for acute cases in the city in which it is situated. It is maintained by the university, is directed by the head of the department of mental diseases, and is used for instruction of medical students. It has about three times as many nurses as the average asylum, and the patients enjoy the most advanced medical care. In all the German hospitals, and in those of Switzerland and Italy as well, a six months' course in the study of insanity is required, and a student can not obtain his degree without undergoing a special examination which includes the clinical examination of patients. The most distinguished alienists are in charge of these hospitals. Kraepelin at Heidelberg needs only to be mentioned to indicate that the greatest specialists in Germany are not too great to be enlisted in the service of the state. Candidates for government physicians must serve as internes in the public asylums, and no physician is allowed to have charge of a private asylum, who has not served two years as interne in a public asylum, while a dozen years of apprenticeship are usually necessary before a man can attain a superintendency of a public hospital. His superintendency attained, his position is permanent during good service. Thus the state obtains its servants by training them and keeps them by the reward, not of great salaries, but of permanent positions and opportunities for scientific work."

The report quotes extensively from that remarkable document published by the French Republic, to which we have already referred in these columns, "The Report on the Care of the Insane," edited by Dr. P. Serieux, and points out the evident freedom from political domination which characterizes the work of Dr. Serieux. "The point of interest in studying the French attitude toward public care of the insane is not the actual situation of the insane in France. That is strangely like our own in the lack of adequate nursing service, and in the demand for 'business administration' by those who are unconscious of the lines of true economy in humanitarian affairs. It is the fearlessness of the French self-criticism, the candor of her recognition of a superior service, even if it be in the land of her dearest foe, her humble willingness to study wherever there is anything to be learned—this state of the official mind it is which must interest and inspire us."

The fact that in America institutions for the insane are carried on by the separate states and that any criticism of their management in any state is likely to be considered as an attack on the dominant political party in that state, renders a candid discussion or comparison extremely difficult, almost sure to offend the politicians in power, and therefore to result in no good to the institutions. Possibly if this important matter could be the subject of federal inquiry we could attain the independent spirit of the French government. Indeed, we look forward with interest to the appearance of the government statistics on the extent of recognized insanity, which, we are informed, are nearly ready for publication. It may be that they will prove a basis for further governmental inquiry.

The report emphasizes the need of popular education and popular respect for medical standards, and refers to the present status of the Cook County Hospital for the Insane (Chicago) as an excellent illustration of the improvement which can be readily secured when good officials have public backing. "The Cook County Insane Asylum offers an instance of an institution recently lifted from neglect and inefficiency to the highest standard by the power of public opinion. The case is especially apposite to our argument, because the public interest was not directed toward changes in business management—no charges of fraud or dishonesty were brought—no effort was made to change the financial methods which are well organized and carried on by the paid Board of County Commissioners. It was to create a spirit of humanity and of science and to apply it to the daily lives of the patients that effort was directed. This asylum has become one of the best-conducted in the world, on the medical and nursing side. The moving force in securing this fundamental improvement was an aroused public attention, which insisted suddenly on knowing about the institution, and next demanded, and at once obtained, a better service. It should be added that a controlling majority of the managing board heartily co-operated in the changes which revolutionized the asylum and demonstrated afresh that official boards in this country must have the backing and stimulus of the intelligent public opinion."

---

[1] Report of the Committee on State Supervision and Administration, made by J. C. Lathrop, Hull House, Chicago, at the National Conference of Charities, Portland, Ore., 1905.

The report closes by stating three essentials for an adequate system of state supervision and administration of public institutions as follows: 1. On the one hand, absolute independence of that exploitation which we know as a "political influence," and, on the other hand, strict accountability to the proper state authorities. 2. The enlistment of the finest trained ability in the public service. 3. A sustained intelligent public interest.

TUBERCULOUS RHEUMATISM.

It must be apparent to all who have followed medical literature for the last few years that the subject of rheumatism has received a good deal of attention. It was surely time that the heterogeneous group of cases which were classed under this name should receive a thorough overhauling. As a result of the restudy of this important subject we have received light on many obscure points, but fresh aspects of the subject have cropped up and need investigation. Among these is the relation which exists between tuberculosis and certain forms of joint disease which do not conform to the classical type of tuberculous arthritis, clinically or pathologically.

Attention was first drawn to these forms of rheumatism several years ago by Poncet, and a great many of the publications on the subject have emanated from this author and his pupils, or from other representatives of the French school. In Germany the matter has received but little attention, while in this country little has been contributed. Only one important contribution on the subject comes to mind, the article of Edsall and Lavenson.[1] The assumption of Poncet and his adherents is that certain forms of joint lesion now classed as chronic rheumatism or arthritis deformans are in reality tuberculous in nature, and due to the action on the joints of the tubercle bacillus or its toxins. Not only chronic forms of rheumatism have been ascribed to this cause, but also certain atypical acute forms. Laub,[2] for example, has recently described as tuberculous rheumatism an attack of acute joint disease, polyarticular in character, in a tuberculous patient with an acute tuberculous pleurisy. The acute form of tuberculous rheumatism is said to differ from ordinary acute articular rheumatism in its atypical course, the moderate swelling and pain in the affected joints, the slight impairment of movement, and the lack of effect of salicylates. This form of the disease is not, however, the most common one, and more frequently we see what Poncet describes as "rhumatisme tuberculeux ankylosant," which is more chronic and results in a dry fibroarthritis with formation of new bone in the neighborhood of the joint. This form generally begins in one joint and gradually involves others. Poncet has also suggested that certain types of what is clinically classed as arthritis deformans should be grouped with tuberculous rheumatism, as they also are due to the tuberculous poison.

The questions brought up by this work of Poncet are important ones, and worthy of careful consideration. If any objection can be made to Poncet's deductions it is that they are founded too much on pure clinical observation, and not enough on bacteriologic and pathologic research. It is, of course, true that many things suggest the possibility of a relation between tuberculosis and rheumatism. The well-known effects of tuberculous infection on the bones, as seen in the classical Hippocratic fingers, the curious and frequently observed family association of tuberculosis and arthritism, and other suggestive but less striking facts are all important. But the mere association of two diseases does not necessarily mean that they bear any causative relationship to one another unless this association is strikingly frequent. There are doubtless many cases of rheumatism corresponding clinically to Poncet's tuberculous rheumatism in which no signs of tuberculosis are present. In one or two instances tubercle bacilli have been demonstrated in fluid from joints which did not at all present the characteristics of ordinary tubercular arthritis, and in still more instances the administration of tuberculin has resulted in general and local reactions in individuals suffering from what seemed to be chronic rheumatism or arthritis deformans.

Such facts are certainly very suggestive, notwithstanding the fallacies connected with the tuberculin reaction. It is probably fair to assume that there are joint lesions due to the tubercle bacillus or its toxins which are clinically those of chronic rheumatism or arthritis deformans. Whether such lesions are as frequent as Poncet would have us believe is another matter. In view of the small number of cases in which careful bacteriologic tests have been made, and considering the accessibility of the joints to investigation, the wonder is that the subject has not been more thoroughly thrashed out before this.

KNOWLEDGE AND WISDOM IN MEDICINE.

It has become the custom to select some motto which seems particularly to represent a basic principle in one's life work, and to have it framed and hung so as often to come under one's eye. We know of no words of wisdom that could be more precious in this respect for the physician to see frequently than certain lines of Cowper, on knowledge and wisdom. It is not an unusual impression among members of the profession that the more practice a man does and the more hospital appointments he holds, the more likely is he to gain that larger wisdom which enables him to diagnose readily and with assurance and so to be of special service in consultation. There is many a "pluralist" among us holding hospital appointments, the duties of which he is scarcely able to fulfill and yet who is not ready to resign because he feels that the apparent experience which they enable him to gain must somehow prove of use to him in adding to his store of medical wisdom. But alas! the "pluralist" in medicine does quite as much harm as the holder of several ecclesiastical appointments to whom therefore the name was first applied. Like his religious prototype, he harms himself and others. For him surely Cowper's words will show the vanity of over-occupation:

> Knowledge and wisdom, far from being one,
> Have ofttimes no connection. Knowledge dwells
> In heads replete with thoughts of other men;
> Wisdom in minds attentive to their own.
> Knowledge is proud that he has learned so much;
> Wisdom is humble that he knows no more.

The quotation was recently published in Osler's farewell address to Canadian and American medical students, and he added some precious words of his own:[1] "What we call sense or wisdom is knowledge, ready for use, made effective, and bears the same relation to knowledge itself that bread does to wheat. The full knowledge of the parts of a steam engine and the theory of its action may be possessed by a man who could not be trusted to pull the throttle. It is only by collecting data and using them that you can get sense. One of the most delightful sayings of antiquity is the remark of Heraclitus on his predecessors—that they had much knowledge, but no sense, which indicates that the noble old Ephesian had a keen appreciation of their difference; and the distinction, too, is well drawn by Tennyson: 'Knowledge comes, but Wisdom lingers.'"

As we read we are reminded of some of the most salient facts in the history of modern medicine: Auenbrugger, plodded along patiently in his small, obscure hospital in Vienna cultivating wisdom rather than gathering information, while the presumedly great medical geniuses who were supposed to be adding to medical knowledge were at work in the general hospital with all its clinical facilities, yet the younger, unknown worker solved one of the most important of diagnostic problems and gave us the first foundation stone of thoracic diagnostics. Young Jenner, as a country practitioner, worked out the problem of vaccination, with all that it was to be of benefit to the race. Corrigan studied hard at his little hospital in Jarvis street, Dublin, which had only six beds altogether, and yet in three years he laid the foundation, practically, of all the assured knowledge that we have with regard to aortic diseases. Surely in medicine it is *multum, non multa* that counts; much wisdom, not the knowledge of many things, and least of all superficial information about many things. The first modern physician, whom we are glad to recognize as a great professional brother, as well as distinguished writer, Rabelais, began the railing at useless information and the volumes of it that so many people consume, and it would be worth our while to take his lessons to heart even in the twentieth century.

---

[1] Medical News and St. Louis Medical Review, Sept. 30, 1905.

CAUSES OF THE DESTRUCTION OF THE BACTERIA IN THE SMALL INTESTINE.

Rolly and Liebermeister,[1] two German investigators, have undertaken to discover experimentally the causes of the destruction of bacteria in the small intestine. Rabbits were employed by these investigators. Their first effort was to find out if the contents of the small intestine were sterile or not. They showed by the number of colonies on agar plates that there were only a small number of bacteria present, there being more in the lower ileum. They next wished to discover if bacteria introduced into the small intestine were killed or their growth hindered. Various kinds of bacteria were introduced into the intestine, the stomach having been previously cut off to prevent the entrance of its contents. The results were the same with all the bacteria employed. It was found that the bacteria, if not too many, were destroyed in part by the intestine, some of them being removed by peristalsis, so that after a certain time the small intestine was almost sterile.

Having shown that the small intestine had a definite bactericidal power, they next endeavored to determine the mechanism of this action. Six possibilities were to be considered—peristalsis, intestinal juices, living intestinal wall, bile, acidity of chyme and alteration of the reaction in different parts of the intestine. By rotation of reagent glasses, containing sterile bouillon and various kinds of bacteria, it was observed that motion had no effect on the growth of bacteria, and the authors concluded, therefore, that peristalsis in itself has no bactericidal power. The fact that bacteria flourish when peristalsis is diminished, causing an abnormal stagnation, is due to other causes. The intestinal juice, pancreatic juice and bile, alone or combined, were found to have no bactericidal action, but on the contrary, to furnish good culture media for the growth of microorganisms. The bactericidal action of the living intestinal wall was next tested. By tying off loops of intestine under otherwise normal conditions, they found soon afterward a diminution in the growth or complete death of the bacteria. The exact cause of this action remains unknown.

---

[1] Deut. Archiv. f. klin. Med., 1905, lxxxiii, p. 413. Abstract in The Journal on page 1284.

It was found further, that if the intestinal mucosa is injured, bacteria can grow unhindered. This bactericidal power of the normal, living intestine is the same whether acting alone or in combination with bile or pancreatic secretion. The acidity of the chyme as it enters the small intestine has an inhibitory effect on the growth of bacteria. If the stomach contents are neutralized many more bacteria are carried into the intestine than otherwise. The authors consider that although peristalsis by itself has no direct effect on the growth of bacteria, by quickly carrying bacteria from a fluid of one reaction to that of another, it serves to prohibit abundant growth, since different bacteria require different reactions for their best growth.

It is worthy of special emphasis that if the mucous membrane of the small intestine is injured an enormous growth of bacteria results. This was found to occur whether the reaction was acid or alkaline. The conclusions are reached, consequently, that the mucous membrane of the small intestine has the power of protecting the small intestine from bacteria by destroying them, and, further, that if the mucosa is inflamed or changed in other ways it loses this power, and the intestinal contents furnish a good medium for the growth of bacteria.

While the results of these investigations on the rabbit can not be applied directly and with full force to human beings, yet they help us to understand better certain phases of intestinal infection in man. Thus it is not improbable that there exists a natural, local immunity of the intestinal wall to the typhoid bacillus, infection with which perhaps can not take place without previous mechanical or chemical lesions of the wall itself. In this way may be explained, at least in part, the fact that so many persons escape typhoid fever under conditions that surely must lead to the presence of typhoid bacilli in the intestinal contents. We know that in times of cholera and dysentery epidemics individuals may harbor the respective bacilli in the intestinal tract without any recognizable harmful results, i. e., without infection. Now, it may be that in such cases there was no disturbance of the intestinal wall sufficient to upset its normal resistance. In connection with this, the suggestion may be made that the acquired immunity to typhoid fever and cholera, which seems to persist long after the disappearance of the newly developed antibodies in the blood, may depend on an acquired local immunity of the intestinal wall.

"PERUNA AND THE BRACERS."

The exposure of the alcoholic nostrum is now fairly complete. Well begun by the *Ladies' Home Journal,* the task was last week well rounded out by *Collier's Weekly.* Samuel Hopkins Adams' article entitled "Peruna and the Bracers" proved even more extended and more informing than was anticipated. Many of his facts are more or less familiar to physicians, but more are not. Medical men should read the article and call it to the attention of their patients. Showing that the drug content of peruna is less than one-half of 1 per cent., and that the alcohol content is about 23 per cent., Mr. Adams appears to make it inevitable that the manufacturer and the retailers of this nostrum are to feel the full weight of the new ruling of the United States Commissioner of Internal Revenue as to the imposition of the internal revenue liquor tax. The cost of peruna being 7 to 8 cents a bottle and the retail price $1, it is not hard to see where the fortunes come from. The direct testimony of the production of intoxication—even of fatal narcosis—as well as of chronic alcoholism, should stir the sense of justice of the most negligent. In the prohibition districts of our southern states the consumption of peruna as an intoxicating beverage is so great that Mr. Adams says a number of southern newspapers are advertising a cure for the "peruna habit." Physicians will be interested to learn from this article that two popular nostrums, one of which is advertised to physicians, are owned by a distilling company. For the injurious traffic in "the bracers" two remedies are proposed: (1) "That the government no longer permit liquors to disguise themselves as patent medicines"; and (2) that the manufacturers be compelled to "label every bottle with the percentage of alcohol it contains." The first is now being applied by the Commissioner of Internal Revenue; the second will be provided for if Congress will enact this winter the pure food and drug bill that is so insistently demanded. Of course, the wide publicity itself is certain to have a marked restraining effect on the innocent purchasers of the disguised alcoholics by persons seeking "medicine." Physicians now can aid the reform in two ways: First, by working hard for the passage of the pure food and drug bill, and second, by exercising moral suasion on the proprietors of the newspapers which are active partners in the destructive trade.

THE UNIVERSAL CRAVING FOR ALCOHOL.

Medical readers are familiar with the statistics of the liquor trade in this and in other countries. The per capita consumption of spirits and malt liquors by all nations is appalling in its proportions, and has long been the occasion for grave concern on the part of thoughtful publicists. Present revelations of the magnitude and ubiquitous pervasiveness of the traffic in alcoholic nostrums are staggering. The per capita consumption of these thinly disguised liquors escapes the statistician, but the rapidly amassed wealth of the purveyors of the fraudulent "tonics" and "bitters" testifies loudly to the tremendous extent of the business. As these exposures proceed, the public sees that many of the active opponents of the open liquor traffic are themselves tipplers. Women, children, clergymen, temperance workers, are the victims of this dreadful trade. All this can mean but one thing, namely, that the craving for alcohol is all but universal. All that is needed to arouse the taste is the first sample, and the canny compounders of the alcoholic nostrum take full advantage of this human weakness, adding to the enormity of their crime by selling their wares under false pretenses. Because of this craving for alcohol the public can not be left to care for itself against the disguised liquors. The label must tell the composition of the nostrum, so that the weak and wholly innocent may be protected.

FOUND DROWNED ON LAND.

A curious fact, if it is such, that may have some medicolegal importance, is reported in the press dispatches from London. A man was found dead in a field near a brook, and the medical testimony was that drowning was the cause of death. The evidence seemed to show that he had fallen into the water and that he had been able to crawl out but had practically drowned on dry ground from the water he had taken in. The possibility of a man's being able to get out of the water and still being unable to free his lungs and therefore practically drowning on dry land is not altogether unsupposable, though little is said of it in works on medical jurisprudence. We should like to know the coroner's verdict in this suggestive case.

HOURS OF SLEEP FOR SCHOOL CHILDREN.

It will scarcely be denied that many of the ills of modern life can be traced to overwork and under-rest. Work and rest are habits and they can be cultivated so as to yield mutually the most productive results. The need for sleep varies with the individual. The average adult requires not less than eight hours in twenty-four. While some seem to be able to do well with less, not a few are better for more. Old persons generally get less—at least they do not sleep so long consecutively; but they can take additional rest with advantage in the middle of the day. Without question, children should invariably secure more than eight hours of sleep in each day. The new-born infant sleeps almost all the time, and the young child should receive a maximum amount of sleep. The growing boy or girl requires a large amount of sleep to compensate for the expenditure of energy in growth and development, and a similar statement is applicable to the youth of both sexes at school. In an interesting communication dealing with some phases of this subject, Dr. T. D. Acland[1] points out that in not a few of the great public schools of England an insufficient number of hours are allowed for sleep, in some institutions in defiance of the recommendations of an appointed medical officer. The conditions are more satisfactory in the United States. As the result of an inquiry among masters and medical officers of schools, physiologists and physicians, the conclusion is reached that growing boys need from nine to ten hours of sleep. Rather more is required in the winter than in the summer. Not only the quantity but the quality of the sleep must be taken into consideration. Among influences contributing to the latter are darkness, freedom from noise and other disturbance, a comfortable degree of heat and proper ventilation. A factor of great importance that is often ignored is the inculcation of the habit of sleep with respect to both regularity and time.

"HUMANE" MURDER.

In his "Blithedale Romance," Hawthorne remarks that the woman reformer, in her attacks on society, has an instinctive sense of where the life lies, and is inclined to aim directly at the spot. However true or otherwise this may be in a general way, there have been striking illustrations of it of late. During the past few months an irregular medical practitioner of the sex usually called the "gentler," strongly advocated, in a meeting of her own sect, the killing off of the degenerates, and was flattered by an extensive press appreciation in the way of quotation and republication. Still more recently, a woman, a delegate to the American Humane Association, offered a resolution asking for the legalization of the murder by anesthetics of persons painfully and fatally injured, and advocated also the same for persons suffering from lockjaw, consumption and other painful and hopeless diseases. Her resolution was very properly ruled out by the presiding officer, but that it should have been offered is a rather striking commentary on the extreme views that are held by some would-be philanthropists. Ill-balanced reformers, with an imperfect or twisted moral sense, are always too common, and the publicity of their vagaries is often a serious drawback to progress in real and necessary reforms. One of the most objectionable facts in connection with this class is the unscrupulousness with which persons like the one referred to claim the indorsement of others for their own peculiar individual hobbies. The woman referred to, it is said, quoted the names of prominent clergymen and others as favoring her idea. Apparently, she did not venture to quote the names of reputable medical men, and for that we are thankful.

THE NEED OF AN ANATOMIC LAW IN TEXAS.

An anomalous condition—at least anomalous at this age—exists in the state of Texas. Practitioners of medicine are required to have a knowledge of the human body and medical colleges are chartered to teach the science and art of medicine in that state, and yet there is no legal provision whereby the student or the physician can secure the dissecting material. To desecrate a grave in Texas is a crime punishable by six months' imprisonment, or a fine of $500 or less. To disinter or to carry away any human body or the remains thereof, or to conceal it knowing it to be illegally disinterred, is a crime punishable by a fine not exceeding $2,000. It is legal to dissect bodies before burial, but it is impossible to secure them legally. In 1900 a measure to legalize means of providing dissection material passed the legislature, but the governor vetoed it. In 1904 a bill was prepared containing provisions which, it was thought, would prevent any of the abuses which had been feared by the public, and yet it was impossible to secure a vote in the senate on the question. The profession of Texas certainly deserves better treatment than this. It has been suggested that in suits for malpractice it would be a legal defense in the state of Texas to show that the laws of the state, if adhered to, prevent the student or the practitioner from securing a working knowledge of the human body, and that, therefore, a suit for malpractice could not stand. The situation demands a prompt remedy, and we trust that our Texas brethren will leave no stone unturned until they are allowed to use unclaimed bodies, instead of the present necessity of resorting to illegal means.

[1] Lancet, July 15, 1905, p. 136.

PRESCRIPTION GRAFT.

Now that lay journals are aiding in the exposure of the evils of the nostrum traffic, there is increasing lay interest and discussion of medical affairs. Thus we find reference to druggists paying commissions to physicians on prescriptions, and of course the practice properly is condemned. It is indefensible, and we hope it is not sufficiently common to need more than passing remark. As the public becomes better posted on these points, the offender in this respect must not be surprised when he meets with exposure and loss of professional standing. Such methods are certain of ultimate discovery, and it is folly to risk one's reputation for so petty and so mercenary a stake.

COLLABORATION OF THE PRESS IN SCIENTIFIC CONGRESSES.

In an able review of the work accomplished by the International Tuberculosis Congress at Paris last month, the *Semaine Médicale* of Paris comments on the way in which the lay press seized the opportunity of the congress to insert advertisements in its reading text. At the opening of the congress the secretary general remarked: "Thanks to the generous and untiring collaboration of the press, not only the scientific, but the literary and political press, this congress will be able to spread throughout the world the idea of the solidarity of all human races in respect to tuberculosis. The seed has fallen into good ground." The article continues: "The lay journals gave plenty of space to accounts of the congress, but these journals—which give such ample hospitality to the flaunting advertisements of shameless irregulars—can they be relied on to propagate sound ideas in regard to the struggle against the redoubtable scourge? No illusions could be retained after seeing in one of these journals the detailed program of the congress followed by a recommendation of an establishment for the cure of tuberculosis. Under the heading 'Tuberculosis Congress,' was the following notice: 'At the moment when the antituberculosis congress is on the point of convening, we must call attention to the cures obtained at the medical institute of ———' (giving the name and address of the institute, hours for consultations, etc.). A few days later, in the same journal, the report of the congress was followed by a paragraph to the effect that 'the omnipresence of the tubercle bacillus is the main point established by the congress, but the destruction of the bacillus is still under discussion. The members of the congress, however, recognized that the ——— company has found the elegant solution of this problem.' After these experiences it would require the optimism of a Pangloss to maintain that a scientific congress can count on the useful collaboration of the political press, and that 'the seed has fallen into good ground.' Unfortunately, it is not in the political press alone that the advertisements press close on the report of the Tuberculosis Congress. We have seen a certain medical journal, in one of its most recent issues, recording the transactions of the congress, devote one-half of each of the congress pages to advertisements of medicines for tuberculosis, dividing the page equally between the congress and the ads." The writer probably refers to the issue of the *Presse Médicale* for October 6, which bears the special heading "Congrès International de la Tuberculose, No. 80 (Supplémentaire)." The upper half of twelve pages is devoted to the congress, while the lower half of eight of them contains a running advertisement of medicines to use in tuberculosis. Our contemporaries across the water have commercialism to hold in check, it seems, as do we on this side.

WOMEN STUDENTS AND THE STUDY OF ANATOMY.

At a recent meeting, the Melbourne University council, according to the *Australasian Medical Gazette*, discussed the question of the accommodation for women medical students in the study of anatomy. It was pointed out that as the women occupy a separate room they are at a disadvantage, and one of the professors expressed a decided opinion in favor of the men and women using the same dissecting room, but he said that the women, in view of opinions being expressed that there was impropriety in the practice, did not care to adopt it. As the *Gazette* points out, if women are to be admitted to the medical curriculum at all, and especially if they attend coeducational schools, they must be prepared to work alongside of men students throughout their whole course; and any suggestion that they should receive separate instruction is based on false sentiment. The two sexes must meet in the postmortem room and in the hospital wards, and if they must be associated in the later part of their curriculum, surely there can be no objection to such a practice when they are studying anatomy. There need be no more impropriety in the conscientious study of human anatomy than in the study of botany or biology; the impropriety is not in the subject, but in the attitude of mind of the student.

"INTERNAL" VACCINATION.

An Iowa judge has recently ruled against a local board of health which had refused to admit to the public schools pupils who had only ingested vaccine matter in the manner endorsed by certain members of the homeopathic school of practice instead of by direct inoculation. It was held that a method of vaccination endorsed by one of the recognized schools of medicine could not be discriminated against by any local health board. It is unfortunate that such matters have to be left to lay judges to decide. THE JOURNAL has already expressed an opinion regarding the value of this method of vaccination. The situation affords an opportunity for some of those who do not advocate this method to observe some of its possible effects.

Therapeutic Misinformation.—Certain writers have asserted that an alkali given before eating always increases the secretion of HCl, and given after meals lessens it. This is not true. This piece of misinformation has been handed down from the time of Sydney Ringer at least.—Boardman Reed.

Medical News

ARKANSAS.

New Hospital.—A new Catholic hospital has been established at *Fort Smith.*

College Opens.—The twenty-seventh annual session of the Medical Department of the Arkansas University, Little Rock, began October 16, the opening address being delivered by Dr. Edwin Bentley, dean of the faculty.

Fined for Prescribing Baths.—Dr. Thomas B. Rider, Hot Springs, was arrested October 3 by a deputy United States marshal on the charge of prescribing hot water baths for patients, he being an unregistered physician. On his trial October 4 he was fined $50 and costs.

Personal.—Dr. John Hern, interne at the City Hospital, Little Rock, has resigned and gone to Tucson, Ariz., for his health. ——Dr. Milton Vaughan has resigned as contract surgeon United States Army and will resume practice in Little Rock. ——Dr. George W. Hudspeth, Little Rock, was operated on for kidney disease October 6 at St. Vincent Infirmary. He is reported making favorable progress toward recovery.——Dr. Edmund D. Shortledge, United States Army, who has been spending some time in Hot Springs, has returned to his home in Wilmington, Del.

CALIFORNIA.

Personal.—Dr. Maude Noble, San Francisco, sailed for home from Antwerp November 4.

County Hospital Too Small.—Although the Los Angeles County Hospital was completed less than a year ago, all but 20 of its 212 beds are occupied, with the worst months for illness—December and January—yet to be heard from. The entire capacity of the hospital is 250 beds.

Guilty of Assault.—Dr. L. T. Holland, Los Angeles, formerly coroner of Los Angeles County, on October 13 was fined $30 for battery on Mrs. Eliza Flick. Mrs. Flick alleges that Dr. Holland struck her a blow on October 3, when she demanded rent due her. The physician claims that Mrs. Flick ran into his fist.

Crusade for Pure Milk.—The board of health of Los Angeles and the city health officer have recently inaugurated a crusade for pure milk. After personal visitation of dairies within and outside of the city limits, followed with analyses by the city bacteriologist, the board has decided that a dairy selling milk which contains more than 500,000 colonies of bacteria to the cubic centimeter shall be the subject of investigation.

Sent to Asylum.—Dr. Frederick W. Harris, San Francisco, appeared before the lunacy commissioners October 8 and begged to be committed to an asylum. After examination he was committed to the Agnew State Hospital.——Dr. W. N. Moore, Ukiah, county physician of Mendocino County, was committed to the Mendocino State Hospital, Ukiah, October 17. He was once elected medical superintendent of this hospital, but lost the position in the legal contest which followed.

Physician Assaulted.—Dr. James F. Rinehart, Oakland, has sworn out a warrant for the arrest of John Rose, a saloon-keeper, on the charge of assault with a deadly weapon. The physician states that he called on Rose to collect a bill of $42.50, but that Rose refused to pay, tendering $25. On Dr. Rinehart's refusal to accept this amount, it is said that Rose picked up a club and, without warning, struck the physician a blow on the head which felled him to the floor insensible.

DISTRICT OF COLUMBIA.

Needs Larger Appropriation.—Dr. William C. Woodworth, Washington, health officer of the district, has asked for an appropriation of $141,240 for the health department for the next fiscal year. This is an increase of $48,460 over the amount asked for last year.

Obstetrical and Gynecological Society.—The annual meeting of the Washington Obstetrical and Gynecological Society was held October 30. The election of officers resulted as follows: Dr. George N. Acker, president; Dr. Miller, secretary; Dr. Prentiss, treasurer, and Dr. Loren P. T. Johnson, corresponding secretary.

Health of the District.—The report of the health officer for the week ended October 21 shows the total deaths to have been 108—white 57, colored 51; births, 131—white 88, colored 43; stillbirths, 16—white 7, colored 9. There were under treatment at the close of the week 29 cases of diphtheria, 8 of scarlet fever, 205 of typhoid fever and 1 of smallpox.

New Medical Society Formed.—The George Washington Alumni Association (medical branch) met October 21 and formed a new medical society for its members. It is proposed to hold meetings monthly during the scholastic year. Dr. A. Barnes Hooe was elected president, Dr. John W. Chappell, vice-president; Dr. Daniel W. Prentiss, secretary, and Dr. Louis Taylor, treasurer.

Report of the Surgeon-General of the Navy.—Surgeon-General Presley M. [illegible], in his annual report recommends enlarging the Naval Hospital at Norfolk, Va., to a capacity of 300 patients, and the establishment of a hospital or camp at Park Royal, S. C., for the care and treatment of tuberculosis. He also recommends extensive improvements in the hospital at Pensacola, Fla.

Hospital Named in Honor of Walter Reed.—By order of the War Department the Army General Hospital, which will be constructed in the District of Columbia, under the authority conferred by the act of Congress approved March 3, 1905, will be known as the Walter Reed United States Army General Hospital, in honor of the late Major Walter Reed, surgeon, United States Army, "whose demonstration of the mode of transmission of yellow fever is of the highest public importance."

Student's Suit Still Rejected.—On October 21 Judge Barnard refused a writ of mandamus to Frank A. Davis, a medical student, who holds a diploma from the medical department of Howard University, and who sought to compel the District Board of Medical Supervisors to allow him to take the examination for a physician's license. The medical supervisors, however, took a different view, holding that a two years' course in pharmacy was not equivalent to one year in medicine and that, therefore, the applicant had not completed the four years' study required by the law.

Freedman's Hospital Report.—In his report to the Secretary of the Interior Dr. William A. Warfield, the surgeon in charge, says:

> The most important event affecting the management of the hospital occurred when Congress, by the sundry civil act, approved March 3, unified the management under the Department of the Interior, in accordance with the recommendation contained in your last annual report. Although it has been only two months since the change became operative the wisdom of the act has been clearly demonstrated, and it is further emphasized by the lack of embarassment which so frequently proceeded from a dual control of the hospital, and the facility with which supplies are now received.
>
> In compliance with the act above referred to, patients from the District of Columbia are now admitted to the hospital on a contract basis. The hospital receives from the board of charities of the District of Columbia $1.10 per day for the care and treatment of all persons over twelve years of age, 65 cents per day for those under 12 years, and 40 cents per day for those born in the hospital, Congress having appropriated $25,500 for the same. This sum will not be sufficient to care for the District of Columbia patients throughout the present year if the rate of admissions continues as high as during July and August.
>
> Two thousand nine hundred and eighteen were admitted, 187 were born in the hospital and 114 were remaining July 1, 1904, making a total of 3,219 under care during the year; 3,066 were discharged, leaving 153 in the hospital July 1, 1905, as against 114 the preceding year. Of the number discharged, 1,997 were cured, 424 were improved, 191 unimproved, 66 not treated and 201 died.

GEORGIA.

Had No License.—"Dr." W. C. Williams, a colored individual of Atlanta, at whose office all diseases were alleged to be cured, was fined $25 and costs September 18 for practicing medicine without a license.

Health Board Wants Prompt Report.—The Augusta board of health has sent out personal letters to the physicians of the city urging on them the necessity of full and prompt reports of all communicable diseases and of births and deaths.

Personal.—Dr. W. Monroe Smith, Atlanta, was fined $15.75 September 27 for exceeding the automobile speed limit.——Dr. Eben G. Russ, *formerly of* Atlanta, who has been ill at St. Mary's, Pa., is convalescent and has been taken to Atlantic City, N. J.

To Observe Ethics.—The Muskogee County Medical Society, at its regular meeting, October 4, adopted a resolution requesting the newspapers of the city not to publish the names of attending physicians in their accounts of accidents. The object of the resolution is to prevent even the semblance of advertising on the part of the physician.

Medical Schools Opened.—The Medical College of Georgia, Augusta, was formally opened October 2 for its seventy-fourth term with an address by Dr. De Saussure Ford.——The Atlanta College of Physicians and Surgeons held its opening exercises October 5, when the new president, Dr. William S. Elkins, and Drs. Hunter P. Cooper, William P. Nicholson and Abner W. Calhoun made short addresses.——The Atlanta

School of Medicine was formally opened October 3 with addresses by Governor Northen and the board of trustees, Drs. William S. Kendrick, Charles D. Hurt and Edward G. Jones. The school applied on the same day for a charter, the application stating that the institution will not be for gain, but that its objects are to teach the practice of medicine, surgery, dental surgery and pharmacy, and to establish a school for training nurses.

Training School for Medical Missionaries.—A training school for medical missionaries was opened in Atlanta September 1. The institution admits both men and women, and the degree of doctor of medicine will be conferred on the completion of the legal requirements and the passage of the examination required by the state. The faculty comprises the following: Dr. James McFadden Gaston, dean of the faculty, professor of principles and practice of surgery, and lecturer on chemistry; Dr. Joseph H. Green, professor of obstetrics and diseases of women, and lecturer on anatomy; Dr. Ephraim Smith, professor of physiology and lecturer on histology and clinical medicine; Dr. Edmond Lee Awtry, professor of materia medica and therapeutics and lecturer on diseases of children; Dr. George Brown, professor of diseases of the eye, ear, nose and throat; Dr. William S. Wood, professor of principles and practice of medicine; Dr. J. Chester King, associate professor of diseases of nervous system; Dr. Walter B. Emery, associate professor of genitourinary diseases; Dr. J. W. Duncan, associate professor of diseases of chest and clinical medicine; Dr. Charles F. Maddox, associate professor of diseases of the eye, ear, nose and throat; Dr. Isaac T. Catron, professor of military and naval surgery, assistant to the chair of surgery; Dr. H. Bak, lecturer on tropical diseases and internal medicine; Dr. Willis B. Parks, professor of psychology; Dr. Ludwig Amster, lecturer on gastrointestinal diseases, and Dr. Thomas C. Longino, demonstrator of anatomy.

ILLINOIS.

Hospital Established.—The Cairo Colored Hospital has been incorporated by Fannie Williams, Nancy Bugg and Adminia A. Watkins to maintain a charitable hospital for the colored indigent sick and a training school for colored nurses.

Civil Service in State Institutions.—By the law which became operative November 1 all the charitable institutions of the state will be under the civil service law. This will carry with it the application of the merit system to the employment of several hundred servants of the state, and should result in the betterment of the care and treatment of the insane, the helpless and the diseased.

Personal.—Dr. Alpheus A. Bondurant, Cairo, has gone to St. Mary's Infirmary for beneficial rest and change after his illness.——Dr. and Mrs. Frederick W. Werner, Joliet, have returned from Washington.——Dr. Fred. J. Parkhurst, Danvers, is taking a trip through Texas and Mexico.——Dr. Edward Bollenger has resigned as a member of the medical staff of the Illinois Eastern Hospital for the Insane, Kankakee.

Military Tract Officers.—At the sixty-sixth annual meeting of the Military Tract Medical Association, held in Canton October 19, th[illegible] were elected: President, Dr. Ralph C. [illegible] vice-presidents, Drs. W. E. Shallenberger, Canton, and John P. Roark, Bushnell; secretary-treasurer, Dr. Franklin E. Wallace, Monmouth; censors, Drs. Joseph B. Bacon, Macomb; Sumner M. Miller, Peoria, and Maude T. Rogers, Cuba; committee on necrology, Dr. William E. Grigsby, Blandinsville. Dr. James E. Coleman, Canton, was appointed delegate from the society to the Senn banquet, in Chicago, November 11.

Anticipating Merit Rule.—The governor has made numerous changes in the staffs of the charitable institutions of the state, to take effect before November 1, when the new state civil service law becomes operative. Among these appointments are the following: Dr. George A. Zeller, reappointed superintendent of the Illinois Hospital for the Incurable Insane, Bartonville; Drs. Walls, Chicago Heights; William H. O. Galland, Charles G. S. Rydin, and Wells, Chicago, at the Illinois Eastern Hospital for the Insane. at Hospital, and Drs. Frank H. Jenks, Aurora, and Ira O. Paul, Winnebago, at the Illinois Northern Hospital for the Insane, Elgin.

Chicago.

Donations to Charities.—The Schwabenverein, at its quarterly meeting, donated $2.500 to the charities of Chicago and vicinity, $1,250 of which went to hospitals.

Stricken with Paralysis.—Dr. Julius W. Oswald, who suffered a cerebral hemorrhage while operating at Alexian Brothers' Hospital, October 31, is reported as slightly improved, but paralysis of the right side remains. He is in a grave condition.

American Academy of Medicine to Meet.—This body will hold its thirtieth annual meeting in Chicago, November 9 to 10. Physicians and others interested will be welcome at the open sessions, November 9 at 11 a. m. and 8 p. m., and November 10 at 10:30 a. m. The program was published in The Journal, October 14, page 1178.

Increase of Diphtheria.—Diphtheria continues to increase most markedly in South Chicago, Kensington and Burnside. Of the 113 cases reported during the week 33 were on the North Side, 28 on the West Side and 52 on the South Side. Of the 52 cases 24 were in the district south of Eightieth Street. Sixteen deaths were reported from the disease during the week.

Deaths of the Week.—During the week ended October 28, 470 deaths were reported, equivalent to an annual death rate of 12.30 per 1,000. Four more deaths occurred than in the previous week and 58 more than in the corresponding week of 1904. Consumption takes the lead in death causes with 61, followed by pneumonia and heart diseases, each with 53; acute intestinal diseases with 45, Bright's disease and cancer, each with 36, and violence, including suicide, with 32.

Antitoxin Always on Hand.—The commissioner of health calls attention to the fact that by the revised municipal code the commissioner of health is required at all times to keep on hand "a sufficient quantity of antitoxin to permit the treatment therewith of any dependent or deserving person who shall apply to him for that purpose, and that he shall, without charge, treat with antitoxin any and all persons who may apply to him for such treatment, and who, in his opinion, require such treatment."

American College of Medicine and Surgery.—This college, the medical department of Valparaiso University, and located at 339 South Lincoln Street, Chicago, has made extensive changes in its policy and in the personnel of its faculty. Formerly an eclectic school, it has ceased to be sectarian and has made application for membership in the American Association of Medical Colleges, claiming that it has conformed its curriculum to the requirements of that body. Many new members have been added to the faculty and the few old members remaining have applied for membership in the Chicago Medical Society. The following are the heads of departments in the reorganized school: Henry S. Tucker, dean, gynecology; Ross C. Whitman, pathology and medicine; Victor J. Baccus, surgery; J. Newton Roe, chemistry; Charles H. Francis, secretary, ophthalmology; Henry F. Lewis, obstetrics; Henry G. Anthony, dermatology, genitourinary and venereal diseases; Leonard L. Skelton, neurology; Robert H. Good, laryngology and rhinology; George J. Tobias, hygiene and preventive medicine; George F. Butler, therapeutics; William L. Copeland, anatomy; Mason L. Weems, physiology.

INDIANA.

In the Hands of the Law.—Leslie N. Beaven, an osteopath of Vincennes, was fined $25 and costs October 18 for practicing medicine without a license.

Diphtheria Epidemic.—The schools of Princeton have been closed on account of an epidemic of diphtheria.——As a result of diphtheria at Newton the public schools of the town have been closed.

Cornerstone Laid.—The cornerstone of the administration building of the Methodist Hospital, Indianapolis, the first and largest of the group of buildings to be erected, was laid with appropriate ceremonies October 25.

Pathologic Laboratory Installed.—The new division of bacteriology and pathology of the State Library of Hygiene, established for the purpose of disease prevention and treatment, will be in operation November 1 under the charge of Dr. T. Victor Keene, city sanatorian of Indianapolis.

District Society Meeting.—The Thirteenth Councilor District Medical Society held its annual meeting at Elkhart October 19, at which Dr. Charles C. Terry, South Bend, was elected president; Dr. John M. Ward, Kewanna, vice-president, and Dr. John C. Fleming, Elkhart, secretary and treasurer. The next meeting will be held in South Bend in March, 1906.

Would Avoid Even Appearance of Evil.—The Clay County Medical Society has adopted a resolution agreeing to call the attention of the reading public to the fact that it is nonethical and beneath the dignity of a scientific profession for physicians to allow their names to be published in connection with local notices of sickness, accidents or surgical operation.

Personal.—Dr. and Mrs. Jonah M. Bye, Indianapolis, are going to Mexico for the winter.——Dr. Reuben E. Brokaw has been elected secretary, and Dr. William P. Schwartz, treasurer, of the Portland City Hospital.——Dr. George C. Mason has succeeded Dr. W. I. West as a member of the school board of Oakland City.——Dr. Lewis C. McFatridge, Atlanta, and daughter, have gone to California.——Dr. John M. Pulliam, assistant physician at Longcliff Hospital for the Insane, Logansport, has resigned and will practice in Fort Wayne.——Dr. Kent K. Wheelock, Fort Wayne, has been chosen as a member of the faculty of the medical department of Purdue University.

KANSAS.

Diphtheria Closes School.—School District No. 51, south of Richland, has been closed on account of the prevalence of diphtheria.

Sentence Commuted.—Dr. Samuel B. S. Wilson, Olathe, who was sentenced to eight months' imprisonment for violating the prohibitory law of the state, has had his sentence commuted by the governor on consideration that the fine and costs be paid.

Practiced Without License.—In the case of "Dr." Renshaw, Pittsburg, charged with practicing medicine without a state license, the defendant was released on his own recognizances, on his promise to procure the money necessary to pay the costs, and his agreement to leave town.

Infectious Diseases.—During September 91 cases of tuberculosis were reported to the State Board of Health and 62 deaths; 294 cases of typhoid fever, with 51 deaths; 224 cases of diphtheria, with 11 deaths; 106 cases of scarlet fever, with no deaths; 58 cases of smallpox, with 1 death, and 72 cases of dysentery, with 18 deaths.

South Kansas Society Election.—At the annual sessions of the South Kansas Medical Society, held at Wichita, October 17-18, the following officers were elected: Dr. John D. Clark, Wichita, president; Drs. Richard H. Haury, Mound Ridge, and William H. Smethers, Moline, vice-presidents; Dr. George K. Purvis, Wichita, secretary, and Dr. Fred S. Brown, Wichita, treasurer.

Personal.—Dr. John Morgan, Iola, has resigned as health officer of Allen County, and Dr. Robert O. Christian, Iola, has been appointed to fill the vacancy. Dr. Morgan has moved to Neosho Falls.——Dr. William G. Muir, mayor of Harper, was shot by a cowboy who was "shooting up the town" October 9, but was not seriously injured.——Dr. Oliver C. McNary, National Military Home, assistant surgeon of the Soldiers' Home, has been appointed chief surgeon of the Pacific branch of the National Home for Disabled Volunteer Soldiers, Santa Monica, Cal.

KENTUCKY.

Changes in Medical Faculty.—As the result of the vacancy caused by the death of Dr. John A. Ouchterlony the following changes have been made in the faculty of the department of medicine of the University of Louisville: Dr. John G. Cecil was made professor of the practice of medicine. Dr. Henry A. Cottell was given the chair of materia medica, and Dr. Edward R. Palmer was assigned to the chair of physiology.

Personal.—Dr. Joseph Barr, Lebanon, has assumed the position of physician at the state penitentiary, Frankfort, made vacant by the death of Dr. Hugh L. Tobin.——Dr. F. P. Thomas, Hopkinsville, has been suffering from an infected wound of the finger.——Dr. H. W. Watts, Long View, has been adjudged of unsound mind and has been committed to the Western Kentucky Asylum for the Insane, Hopkinsville, for treatment.——Dr. William Sanders, Louisville, has been made lecturer on the practice of medicine in the Kentucky School of Medicine.

LOUISIANA.

As a Dangerous Character.—Joseph Albert, self-styled "oriental professor," industrial mechanic and chronic disease curer, was fined $25 for practicing medicine without a license and was sent to the Orleans parish prison, New Orleans, as a dangerous and suspicious character, October 14.

Entrance Not Graduation.—Dr. Felix A. Larue, New Orleans, requests us to correct a news note which stated that he recently visited his alma mater at Emmittsburg, Md., to celebrate the silver jubilee of his graduation. Dr. Larue entered the institution in 1880 and the jubilee was of his entrance to St. Mary's College.

Personal.—Dr. Joseph Darracott, Shreveport, has resigned his position in the Shreveport Sanatorium and has accepted a position in the Cotton Belt Railway Hospital, Texarkana, Ark. ——Dr. Norwood K. Vance, assistant health officer of Shreveport, has resigned.——Dr. Thomas Y. Aby, assistant quarantine officer at Quarantine, at the mouth of the Mississippi, has resigned owing to advancing years and ill health.——Dr. and Mrs. Joseph S. Hebert, New Orleans, have returned from a two months' stay in the North and East.

MAINE.

Smallpox.—East Machias reports that at the close of the week ended October 14 there were 7 cases of smallpox of mild type in the town.

Golden Wedding.—Dr. and Mrs. James M. Bates, Yarmouth, celebrated the fiftieth anniversary of their wedding October 11.

Hospital News.—The new North Arostook General Hospital at Eagle Lake Mills is almost completed.——The contract for the enlargement of the Chipman Memorial Hospital, Calais, has been let and work will begin at once. The estimated cost of the addition is $6,000.——Webber Hospital Association, Biddeford, formed several years ago to erect a hospital in that city, has been offered a tract of land as a site for the institution.

Suicides.—Dr. A. G. Young, registrar of vital statistics, reports that during the past year 77 persons committed suicide in the state, 27 more than last year. Of that number 60 were males and 17 females. Of those who committed suicide 21 hung themselves, 21 died from gunshot wounds, 15 were drowned, 13 took poison, 4 cut their throats, 2 jumped from high places and 1 died from asphyxiation.

Personal.—Dr. Albion G. Young, Augusta, secretary of the State Board of Health, and wife, have gone to the Pacific Coast.——Hugh F. Quinn, a senior student in the Medical School of Maine, Brunswick, has been appointed a state bacteriologist.——Dr. Daniel W. Wentworth, Sanford, who has been ill with rheumatic fever, is improving.——Dr. John F. Stevens, Millinocket, has been appointed a member of the local board of health.——Dr. Harvey L. Jewell, Bangor, after a long illness with sciatica, has assumed practice.——Dr. Sarah L. Hunter, Machias, has taken a trip to the Pacific Coast.——Dr. and Mrs. Frederick Thayer, Waterville, have gone to Mexico.——Dr. and Mrs. Ralph W. Bucknam, Portland, returned to California October 20.

MARYLAND.

The Mosquito Question.—A public meeting on the mosquito question was held at the Johns Hopkins University, Baltimore, November 1, at which Prof. John B. Smith, state entomologist of New Jersey, delivered an illustrated lecture.

Recovery from Anthrax.—Dr. Arthur D. Mansfield of Owings' Mills has just recovered from a severe attack of anthrax supposed to have been contracted in Kent County August 17 from an abrasion on his neck caused by the rubbing of his collar, which became infected by contact with some straw on which an infected animal had been lying. He underwent fifteen operations.

Society Election.—The Worcester County Medical Society held its annual meeting at Snow Hill October 24. It was organized two years ago by Dr. William S. Thayer of Baltimore, and embraces in its membership 18 of the 24 physicians in the county. Six were added at the meeting. The following officers were elected: President, Dr. John S. Aydelotti, Snow Hill; vice-president, Dr. Edwin J. Dirickson, Berlin; secretary, Dr. R. Lee Hall; treasurer and delegate to the State Society, Dr. Paul Jones, Snow Hill, and attorney, Mr. Robley D. Jones.

Personal.—Dr. Lewellys F. Barker delivered an address before the Library and Historical Society of the University of Maryland, Baltimore, October 26, on "The Ordering of Life." Dr. Barker has been elected president of the Medical Journal Club.——At the annual meeting of the Society of the War of 1812 Dr. James D. Iglehart was elected vice-president, and Drs. Charles E. Sadtler and Nicholas L. Daspiell were elected members of the executive committee, all of Baltimore.——Dr. John T. O'Mara, resident physician to St. Agnes' Hospital, Baltimore, resigned November 1.——Dr. Montgomery Higgins, Boyds, has gone to Panama under assignment by the government on the medical staff.

MASSACHUSETTS.

Diphtheria Closes School.—The South Street school, Ware, has been ordered closed for two weeks on account of the prevalence of diphtheria.

The Leper Home.—The State Board of Charities has officially visited the State Leprosarium on Penikes Island, of which Dr. Louis Edmonds, Harwich, was recently appointed superintendent.

Wins Suit from Railroad Company.—In the case of Dr. John A. Fitzhugh, Amesbury, vs. the Boston & Maine Railroad, in which the plaintiff claimed damages of $1,250 for himself and of $300 for loss of horse, damage to carriage, etc., the jury found for the plaintiff.

Hospital Notes.—Mrs. Henry Haywood and Miss Helen R. Haywood will erect a hospital at Gardner to the memory of the late Herman Haywood, and will in addition give a sufficient endowment for its maintenance.——Marlboro Hospital will receive $501 as the result of the field day September 16.

Pleads Guilty.—Mrs. Annie Brown, who pleaded guilty to having been an accessory before the act at a criminal operation on Mrs. Elsie Allen, Winthrop, was found guilty October 18 and sentenced to imprisonment in the Women's Reformatory at Sherburn, for five years and three months.

Thurber Society Election.—At the fifty-second annual meeting of the Thurber Medical Society, held at Milford October 12, Dr. Nathan W. Sanborn, Belingham, was elected president; Dr. Osman C. B. Nason, Medway, vice-president; Dr. Ambrose J. Gallison, Franklin, secretary; Dr. Charles B. Hussey, Franklin, treasurer; Dr. Christopher D. Albro, Milford, librarian; Dr. Wilfred W. Browne, Blackstone, orator, and Dr. E. L. Hill, Millis, alternate.

Personal.—Dr. John H. Lindsey, Fall River, has reconsidered his resignation as a member of the staff of the City Hospital.——Dr. Charles Harrington, Boston, secretary of the State Board of Health, has gone to Europe, and Dr. George P. McGrath, his assistant, is attending to the duties of the office.——Dr. Alfred I. Noble, Worcester, has been elected superintendent of the Michigan Asylum for the Insane, Kalamzaoo, to succeed the late Dr. William R. Edwards.——Dr. Edgar Dwight Hill, Plymouth, has been appointed a member of the board of trustees of the Medfield Insane Hospital.

MICHIGAN.

Personal.—Dr. Iman Wisse, Grand Rapids, has been ordained as a minister of the Congregational church.——Dr. Austin O'Leary has been appointed assistant at the Sorsen Private Hospital, Laurium.——Dr. William J. Robinson has been appointed city physician of Lapeer.

Diphtheria.—Menominee is alarmed at the present outbreak of diphtheria in the city.——In Washington Island business is practically at a standstill from the general quarantine, and several deaths have been reported.——In Grand Rapids 30 cases have been reported in two days and the Congress Street school has been closed pending fumigation.——Schools have been closed indefinitely at Camden and all exposed people have been quarantined on account of the prevalence of the disease.

State Board of Health.—At the meeting of the State Board of Health in Lansing October 13, the board ordered printed a new and amended edition of 20,000 copies of "The Dangerous Communicable Diseases, How Restricted and How Spread"; the secretary was instructed to revise certain of the publications of the board and to prepare the same in the form of a manual for the use of local health officers, and a new edition of 2,000 copies of the amended pamphlet on "Embalming and the Removal and Transportation of Dead Bodies" was ordered printed.

Opposed to Contract System.—At the annual meeting of the Pontiac Medical Society October 17 the following resolutions were adopted regarding contract and lodge practice:

> WHEREAS, In recent years there have been frequent calls on the members of our society to render medical and surgical services to individual members of orders, lodges or societies at contract prices; and,
>
> WHEREAS, Some of our members have been prevailed on to render an indefinite amount of service for a definite fee: therefore,
>
> *Resolved*, That the Pontiac Medical Society hereby places itself on record as opposed to the lodge or contract system, so called.
>
> *Resolved*, That the executive committee of this society be asked to present at our next meeting some of the more cogent arguments for such action in the form of a circular letter, which may be sent to each of our members.

The following officers were elected: President, Dr. Nathan B. Colvin; vice-president, Dr. George H. Drake; secretary, Dr. Carlton D. Morris, and treasurer, Dr. James J. Murphy.

MINNESOTA.

Personal.—Dr. Emil C. Robitshek, Minneapolis, has returned from abroad.——Dr. John M. White, LeRoy, has been appointed assistant physician at the St. Peter State Hospital for the Insane, vice Dr. Charles E. Burleson, resigned.

Death Prevents Trial.—The indictment against Arthur Klementz, St. Paul, charged with practicing medicine without a license, was stricken from the docket October 17, as the defendant had died since the indictment was turned in.

Defer Bequests.—The board of regents of the University has asked that the $150,000 bequest for the Elliot Memorial Hospital on the college campus be deferred until the legislature can approve the gift and make provision for the maintenance of the institution.

Hospital Fire.—St. Raphael's Hospital, St. Cloud, was destroyed by fire, which started near an elevator shaft, October 10. Fifty-three patients and 16 sisters of the Order of St. Benedict were removed in safety. The loss is estimated at $60,000, with an insurance of $33,000.

Brown-Redwood County Medical Society.—At the annual meeting of this society September 12, Dr. James L. Adams, Morgan, was elected president; Dr. Jacob W. B. Wellcome, Sleepy Eye, vice-president; Dr. W. A. Brand, Redwood Falls, secretary, and Dr. Christopher P. Gibson, Redwood Falls, censor.

Grave Charges.—Dr. H. M. Bracken, secretary of the State Board of Health, charges that the city health office of Minneapolis has directly violated the state laws relative to the inspection and licensing of maternity hospitals. He stated that the records of the State Board of Health show only one duly licensed maternity hospital in Minneapolis, and that he was unable to find records of any inspections during the last two years.

Must Report Accidents.—In accordance with a measure enacted by the legislature, physicians are required to report to the registrars of deeds of their respective counties all accidents which come under their care, providing the patients are incapacitated from pursuing their usual vocations for a period of at least two weeks. Any failure to make such reports on the part of physicians renders them liable to a fine of $100 or imprisonment of six months.

Hospital News.—At a meeting of the directors of the City and County Hospital Association, Albert Lea, September 22, it was decided to lease the Wilcox Hospital and to take charge of it as soon as possible.——The Norwegians of the Northwest have united and will erect a $200,000 hospital in Minneapolis, to be known as the United Norwegian Lutheran Hospital. Drs. Knut Hoegh and Alfred N. Bessesen are members of the board of trustees. Dr. Henry Nissen has given $1,000 toward the building fund.——The new hospital at Luverne was formally opened October 16. The building has been erected by Dr. A. E. Spalding at a cost of $10,000, and is well built and thoroughly equipped.——Drs. Helen and Jane C. Hughes, Mankato, have remodeled and equipped a building as a maternity hospital, which was opened October 16. The institution has accommodations for 15 patients.

MISSOURI.

Academy Wants to Build.—The Kansas City Academy of Medicine, at a meeting October 9, decided to purchase land and build a clubhouse at a cost of $30,000.

Quarantine Hospital.—The House of Delegates has passed a bill appropriating $75,000 for the construction of a hospital at quarantine, south of St. Louis.

Sanatorium Located.—Chigger Hill, north of Mount Vernon, has been selected as the site for the State Sanatorium for the Treatment of Tuberculosis. The site comprises 190 acres and is well adapted for the purpose.

Hospital News.—On October 18 the new St. Mary's Hospital, Jefferson City, was dedicated with appropriate ceremonies. The building will accommodate about 60 patients and has cost nearly $100,000.——The receipt of a check for $2,500 insures to Carthage a hospital to cost $25,000.

Schedule of Clinics.—The schedule of clinics for the medical college season at the City Hospital is as follows: Monday and Saturday are given to the eclectic and homeopathic schools respectively; Tuesday to the College of Physicians and Surgeons; Wednesday to the Washington University; Thursdays to Barnes Medical College, and Friday to the Marion-Sims Medical College.

Southwestern Doctors Meet.—The John T. Hodgen Medical Society, embracing the counties of Cass, Bates, Vernon and Barton, held its annual meeting in Nevada October 5. The following officers were elected: Dr. McCord G. Roberts, Lamar, president; Drs. Theodrick C. Boulware, Butler, and M. P. Overholzer, Harrisonville, vice-presidents, and Dr. Thomas F. Lockwood, Butler, secretary and treasurer. The next meeting will be held in Lamar.

Personal.—Drs. S. B. Wells and Joseph E. Dibble, Kansas City, have been appointed official vaccinating physicians.——Dr. Moritz F. Weymann, St. Joseph, was committed to State

Hospital for the Insane No. 2, St. Joseph, September 30.——Dr. Avis E. Smith, Kansas City, was given the degree of M.A. at the recent convocation of the University of Illinois.——Dr. Mary H. McLean, St. Louis, has returned from a trip to the Orient.——Dr. George B. Thompson, Kansas City, is in a serious condition from an accident received a month ago on the Leavenworth electric line.

MONTANA.

Charge Dismissed.—The charge against H. De Pew, Anaconda, of practicing medicine without a license, has been dismissed on motion of the assistant county attorney.

Practiced Without License.—A. R. Lucas, Bozeman, charged with practicing medicine without a certificate from the State Board of Examiners, was found guilty October 11 and was fined $100 and costs, a total of $170.80.

Hospital Notes.—A hospital has been opened in Red Lodge by Dr. Samuel M. Souders.——The Murray-Freund Hospital, Butte City, will be known hereafter as Murray's Hospital and will be under the direct supervision of Dr. Thomas J. Murray.

Personal.—Dr. Dan J. Donohue, Glendive, has been commissioned captain in the Second Infantry, Montana National Guard.——Dr. Havelock H. Hanson, Butte, was thrown from his buggy in a runaway accident and sustained a bad fracture of the left arm below the shoulder and an injury to the left knee.——Dr. Malcolm G. MacNevin and family, Butte, have gone to Europe.

NEBRASKA.

Colleges Opened.—The University of Nebraska College of Medicine, Omaha, opened September 28.——The Creighton Medical College, Omaha, was opened September 30.

Fever at Insane Hospital.—The Nebraska Hospital for the Insane at Lincoln is suffering from a serious epidemic of typhoid fever; 19 cases have already appeared.

Personal.—Dr. Ernest J. C. Sward, Oakland, has succeeded Dr. Andrew B. Summers, Omaha, as secretary of the State Board of Health.——Dr. Samuel K. Spalding, Omaha, has been elected health inspector.——Dr. Edwin Oxford, Omaha, has been made assistant physician of the Latter Day Saints' Hospital, Salt Lake City.

Attack Legality of State Medical Board.—The attorneys for Drs. Erick Munck and D. G. Walker, Platte County, whose medical certificates were revoked several months ago by the State Board of Health, have filed briefs in the Supreme Court in which they question the legality of the statute providing for the establishment of that body. It is charged that the statute is violative of the constitutional provision that requires all fees of office to be paid in the state treasury.

NEW HAMPSHIRE.

Bequest.—By the will of Mrs. Edward C. Thayer, Keene, $10,000 is devised to the New England Hospital for Women and Children, Boston.

Fire in Sanatorium.—The North Elm Street residence of Dr. Noel E. Guillet, Manchester, was destroyed by fire September 10, with a loss of $3,500, entirely covered by insurance.

Would Force Contract Practice on Physicians.—At a convention of delegates representing fraternal benefit societies of Nashua resolutions were adopted protesting against the action of the Nashua Medical Society in agreeing to refuse to enter into any contract with fraternal societies or to hold consultations with contract physicians of such fraternal societies.

Hospital News.—Rev. Jeremiah S. Jewett, Warren, has offered $3,000 worth of real estate as a site for a hospital for Laconia. When $10,000 has been secured a bequest made by Rhoda Ladd will be available.——A friend of Dr. William J. W. Beattie, Littleton, who does not wish his name made public, has offered $5,000 toward the erection of a hospital in that town and $1,000 a year for the next five years, provided the town of Littleton will support the project.

NEW YORK.

Gift Fair Open.—The German Hospital gift fair opened at City Convention Hall, Buffalo, October 30, to continue for one week. It promises to be the largest fair for a public charity ever conducted in Buffalo and a huge financial success is to be expected.

Personal.—Dr. Robert A. Taylor, Otisville, has been appointed surgeon by the contractors in charge of constructing the Erie tunnel at that place and a hospital equipment has been installed in his home.——Dr. Robert Abbe, New York City, has been elected president of the Associate Alumni of the College of the City of New York.——Dr. James E. King has been elected a member of the staff of the Buffalo General Hospital.——Dr. Regina F. Keyes has been appointed an assistant on the gynecologic service.——Dr. Max Breuer has returned from several months in Europe.

Central Medical Society.—The Medical Association of Central New York held its annual meeting at Buffalo, October 24. The following officers were elected: President, Dr. David M. Totman, Syracuse; vice-presidents, Drs. William B. Jones, Rochester, and Lemuel L. Tozier, Batavia; secretary, Dr. Clarence A. Greenleaf, Rochester, and treasurer, Dr. William M. Brown, Rochester. The meeting was held in the Historical Society building at Buffalo and was presided over by Dr. Charles G. Stockton. At the close of the meeting the members were entertained by a supper and smoker at the Buffalo Club.

New York City.

To Build Hospital Pavilions.—The commissioner of charities has filed plans for seven emergency hospitals to be erected on Blackwell's Island. They are to be 20 feet front and 100 feet deep and will each have 28 beds. The cost of the group is estimated at $17,150.

Tuberculosis Hospital Assured.—The board of estimate has appropriated $800,000 toward the construction of the proposed tuberculosis hospital on Staten Island, and has bound itself by resolution to appropriate the balance of the $2,000,000 needed to carry out the plans in detail.

Panic in City Hospital.—Fire destroyed a small frame structure on Blackwell's Island adjacent to the City Hospital. This precipitated a panic among the inmates of the Almshouse and City Hospital, which for a time threatened to be serious, and required all the efforts of physicians, nurses and attendants to allay.

The Williamsburg Hospital.—This institution has added to its staff Dr. Glentworth R. Butler, Brooklyn. The service of the hospital has become so large that at a recent meeting of the board of directors it was stated that negotiations were under way to purchase the adjoining property to make room for the increased service.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended October 21, 326 cases of tuberculosis, with 151 deaths; 218 cases of diphtheria, with 28 deaths; 113 cases of measles, with 2 deaths; 99 cases of typhoid fever, with 17 deaths; 75 cases of scarlet fever, with 6 deaths, and 10 cases of cerebrospinal meningitis, with 8 deaths.

Smallpox at Ellis Island.—An immigrant taken from the *Nord Amerika* with a well developed case of smallpox is in the Kingston Avenue Hospital for Contagious Diseases, Brooklyn. The passengers who occupied the same compartment with him, 59 in number, are at Ellis Island awaiting developments. The ship had passed quarantine before the case was discovered.

Water Plan Approved.—The board of estimate and apportionment has approved the report of the board of water supply, providing for the outlay of $161,000,000 for tapping the Catskill Mountains and bringing to the city 660,000,000 gallons of water daily in addition to the present supply. This will give a supply sufficient for all purposes for the next twenty years.

Sterilized Milk Urged.—Mr. Nathan Strauss of this city read a paper before the Milk Congress of Paris as to the need of pasteurizing the entire milk supply of cities. Dr. Harvey W. Wiley, chief of the bureau of chemistry, has given his unqualified indorsement to Mr. Strauss' suggestion that the pasteurizing of milk should be made a municipal function and that it is quite as important that pure milk should be furnished to cities as that they should have pure water.

New Hospital Ready.—The Philanthropic Hospital which was recently chartered by the State Board of Charities, was dedicated October 29. The temporary building is located at the corner of Briggs Avenue and Maple Street, Williamsbridge, and the permanent hospital will be in the immediate vicinity. A training school for nurses will be maintained at the hospital, and an ambulance service will be established in a short time. Louis Mann organized a concert a short time ago for the benefit of this institution which netted $1,000.

OKLAHOMA.

Diphtheria.—The public schools at Blackwell and Perry have been closed on account of the prevalence of diphtheria, and at Blackwell church services have been discontinued for the same reason.

Personal.—Dr. G. F. Border, Mangum, who was in charge of the Emergency Hospital at Snyder after the tornado last May, was presented with a handsome medal for his services in that emergency.——Drs. H. Coulter Todd and Ulbus L. Russell, Oklahoma City, are studying in London.

Medical College Opens.—The medical department of Epworth University opened for its second annual session October 12. Only the first two years of a medical course have thus far been taught, but with increased hospital facilities the school will open for a full four years' course in 1906.

Oklahoma City and Not Guthrie Hospital Closed.—The superintendent of the Guthrie Hospital requests us to state that that hospital has not closed, but is enjoying a very flattering success. The hospital which closed owing to disagreement of the staff regarding its management was the Oklahoma City Hospital, Oklahoma City.

PENNSYLVANIA.

Personal.—Dr. Horatio C. Wood was guest of honor at the annual meeting of the Pittsburg Alumni Association of the University of Pennsylvania, October 20.

Typhoid at Nanticoke.—The number of cases of typhoid fever reported at Nanticoke thus far is nearly 400, and the total number of deaths reported thus far is more than 40.

Philadelphia.

Dr. McCracken to Go to China.—At the recent meeting of the board of directors of the Christian Association of the University of Pennsylvania it was resolved to send Dr. Josiah C. McCracken to China for a period of one year in order to study the situation on the field and arrange details of establishment of the proposed medical school in Canton.

Personal.—Dr. Charles B. Penrose has resigned from the advisory board of the Department of Health and Charities. ——Dr. Thomas W. Jackson, U. S. A., will deliver a series of lectures on tropical medicine in the Jefferson Medical College during the term.——Dr. and Mrs. Walter Lindley of Los Angeles, Cal., visited this city during the week and were entertained at dinner by Dr. E. E. Montgomery, October 30. Dr. Lindley is dean of the Medical College of Southern California and editor of the *Southern California Practitioner.*

Health Report.—The deaths reported from all causes during the week numbered 410. This is an increase of 12 over last week, and an increase of 3 over the corresponding period of last year. The principal causes of death were: Typhoid fever, 5; diphtheria, 14; tuberculosis, 52; cancer, 16; diabetes, 6; apoplexy, 24; tetanus, 1; heart disease, 44; acute respiratory diseases, 33; enteritis (under 2 years), 25; enteritis (over 2 years), 6; Bright's disease, 38; suicide, 2, and accidents, 22. There were 200 cases of contagious disease reported, with 22 deaths, as compared with 212 cases and 16 deaths during the preceding week.

Food Adulterators Imprisoned.—The cases known as the "Navy Yard food cases" were tried in court October 26. The defendants were charged with furnishing oleomargarine to the men at the Navy Yard instead of butter. Two firms were found guilty and sentenced to sixty days in jail, to pay a fine of $250 each, and ordered to pay the cost of the prosecution. At the same time Fred M. Hall, the manager of Swift & Co., beef dealers, paid a fine of $100 for selling to the Navy Yard sausages preserved with boric acid. He was also ordered to pay the costs, not only of court, but also of the test which proved the presence of the adulterant in the sausage. An estimate of these costs by an attaché of the dairy and food commissioner's office placed them as high as $1,000.

GENERAL.

Dr. Herzog Studies Beriberi.—Dr. Maximilian Herzog, who for the last two years has been connected with the government laboratories of Manila, has been studying beriberi in the military hospitals of Japan for the past three months, by order of the government of the Philippines.

Removal of Quarantine Against the Isthmus.—The quarantine which the island of Jamaica has maintained against Colon during the past six months has been removed, and the Royal Mail Line of steamships is now permitted to take passengers to Jamaican ports. *Public Health Reports* states that large numbers of Jamaican negroes have been waiting for this opportunity to return to their homes in Jamaica, and the removal of this quarantine will be a considerable relief to the Isthmus.

The Title of Surgeon-General.—It is reported from Washington that Dr. O'Reilly, surgeon-general of the Army, has called attention to the fact that the respective heads of the Navy Department and of the Public Health and Marine-Hospital Service bear the same title of surgeon-general, alleging that in time of war it might cause dire confusion. As the head of the Army Department has borne the title longest, Dr. O'Reilly thinks that the heads of the other departments should be designated in some other way.

Health Report of the Philippines.—The report of the Board of Health of the Philippine Islands states that during June, 1905, there were 583 births in the city of Manila, 295 males and 288 females. During the month there were 627 deaths, of which 593 were of residents and 34 transients. Gastroenteric diseases were especially prevalent among children under 2 years, 84 deaths being caused by gastroenteritis and diarrhea among children of that age. There were 7 cases of bubonic plague, with 6 deaths, and 3 cases of smallpox, with 1 death.

Yellow Fever News.—During the week New Orleans has had a day when no new cases were reported, while the new cases at Pensacola have exceeded those at New Orleans. President Roosevelt has been at New Orleans, where enormous crowds gathered, but as the fever was practically extinct there was little or no danger to anyone.——Failure of citizens and physicians at Pensacola to report cases having practically nullified the efforts to exterminate the infection, drastic action was taken. Dr. L. C. Phillips and Dr. James S. Herron of Pensacola were arrested for failure to comply with the notification ordinance.——Chattanooga, Tenn., abolished its quarantine on October 26.——The northern part of Alabama has been freed from quarantine. At Castleberry, in southern Alabama, there have been two cases of fever whose origin thus far has not been discovered.——The Arkansas quarantine has been abolished except as to two counties on the Louisiana border. ——Texas raised its quarantine as to the uninfected parts of Louisiana and Mississippi.——On October 25 only 5 cases of yellow fever were known to exist in the republic of Mexico. It is hoped that next year will pass without any case.——As a result of the late calamity, New Orleans will have a permanent emergency hospital and a permanent sanitary organization. Unofficially it is announced that there will be a considerable surplus left of the fund raised ($250,000) to fight the fever. This balance will be used for the permanent emergency hospital.——A freak of the epidemic is the estimate made by certain newspapers that the arsenic craze led to the sale and self-administration of 3,000,000,000 tablets—about 6 tons.—— Surgeon White, United States Public Health and Marine-Hospital Service, who conducted the winning campaign at New Orleans among compliments and the thanks of citizens, is the victim of a mal apropos incident. On John H. Whyte, a reporter on the staff of the *Daily States*, has sued Surgeon White for $10,000 damages. Early in the epidemic the correspondent used his name in such a way as to have it confused with the officer's. Dr. White promptly explained the true state of affairs, and his remarks are made the basis of the suit. ——The coming Chattanooga conference on quarantine, a direct result of this season's epidemic, will, it is said, mark a long step toward better conditions.

CANADA.

Trachoma in Canada.—In 1901 the American authorities instituted surveillance over emigrants arriving by way of Canada and turned back those presenting evidences of trachoma. This led to the accumulation of a number of cases in Canada, and, for the first time, the attention of the Canadian government was attracted to the subject of trachoma. In 1902 the regulation was adopted excluding from the country the emigrants with severe cases of the affection, while those with the apparently curable form were taken into the Canadian hospitals and discharged when cured. In 1904 detention hospitals were organized at Quebec and placed in charge of Dr. P. H. Bryce, and here all the emigrants with signs of trachoma are sent for treatment and final judgment on their case. During the year about 800 emigrants were sent to these hospitals and 300 were sent back to the country whence they had emigrated. In 1905 about 1,000 persons have already been sent to the detention hospitals. This large number is due to the increased immigration, and also to the fact that one ship had 330 passengers affected with trachoma from accidental contagion during the nineteen days' voyage. Most of these persons were released after two or three weeks. The steamship companies are beginning to realize that it is to their interest not to bring over trachoma subjects, and during the last few months not a case has been found among the emigrants. The Quebec hospitals also report very few cases under observation during the last year or so, but physicians in the Northwest write that they seem to have an unduly large proportion of trachomatous patients. They are probably old cases, in emigrants who entered the country before the present regulations were enacted. The difficulty of differentiating incipient trachoma from ordinary conjunctivitis renders the question one of the most puzzling that a physician is called on to decide.—From article by J. D. Page, of Quebec, in *Bull. Med. de Québec,* for September.

FOREIGN.

Plague in the Argentine Republic.—It is reported from Buenos Ayres that in the beginning of October there was a recrudescence of plague in Choya.

A Medical Hotel at Rome.—The *Riforma Medica* states that a medical hotel or sanatorium is to be constructed at Rome, equipped according to the most modern ideas of comfort and medical care and attendance.

Medical Social Club at Rio de Janeiro.—A club for social and benevolent purposes has been organized at Rio de Janeiro, the membership being restricted to physicians. The club meets at present in the rooms of the Academy of Medicine. There are 300 members.

Typhoid in Great Britain.—The health officer from Stoke-on-Trent has reported an outbreak of typhoid fever at Trent Vale, which he attributes to the water supply. Bacteriologic examination has shown that a certain well is polluted with sewage to a dangerous extent.

Asiatic Cholera on a British Vessel at Suez.—The steamship *City of Manchester* arrived at Suez from India with one case of cholera on board. The patient, a Hindoo sailor, was landed at the quarantine station, where a bacteriologic examination confirmed the diagnosis. The patient died.

Circular for Workers in Lead.—The German board of health has issued a circular to be distributed to painters and other workers in lead, informing them of the way in which lead poisoning occurs, and means to prevent it. The circular is worded in a concise, popular style and is given free to all interested in the subject, and can be purchased at the news stands.

Yellow Fever in Central America.—Minister Coombs reports from Guatemala City that the epidemic of yellow fever which has been present on the north coast of Guatemala and as far inland as Zacapa and Gualan, has apparently run its course and that conditions are greatly improved. The government has maintained a military quarantine around the infected region.

Medals Awarded by the Tuberculosis Congress.—The recipients of the medals are, Drs. Robert Koch and P. Brouardel, Bang of Copenhagen, Biggs of New York, Broadbent of London and von Schroetter of Vienna. In our mention of the award last week we included the name of Dr. Billings of New York on very reliable authority, but later reports omit his name and give that of Dr. Herman M. Biggs.

Society for the Prevention of Tuberculosis.—It is reported that a society is being formed in Chester for the prevention and cure of consumption. The object of the association is to furnish gratuitous treatment to the poor. Patients will be received and examined and special attention will be given to children. The danger from sputum will be explained, as well as the value of fresh air in promoting recovery.

Proposed National Memorial to Dr. Barnardo.—Appeals are being published in England for the endowment of a fund of a million and a quarter dollars as a national memorial to the late Dr. Barnardo to insure the maintenance of the Barnardo homes for waifs. The appeal states that the number of children rescued, trained and placed out in life by these homes now amounts to 55,962. The work is going on the same since the death of the founder.

Hospitals in Cambogia, Indo-China.—The French resident in Cambogia is organizing a hospital service for that country. The French correspondent of the *British Medical Journal* states that some months ago it was decided to build a native hospital and maternity, and it is expected that the first block will soon be completed. The king, who realizes the benefits to the people of the proposed innovations, has expressed his willingness to defray part of the expense.

Experimental Research on Tuberculosis Infection.—The *Riforma Medica* for September 23 states that Fatta and Cosco have been conducting research at Rome under the auspices of the local board of health to decide whether man can be affected with tuberculosis from animals and *vice versa.* After long, careful experimental work they announce their conclusions to the effect that sputum from persons affected with pulmonary tuberculosis is incapable of infecting tuberculous cattle.

Physicians Elected to Spanish Senate.—The last *Siglo Medico* brings word that ten physicians were elected senators during the election just held. Taboada was appointed a senator for life by the government; Calleja is another physician who has long been a life member of the senate. The National Academy of Medicine has also the right of electing a senator, this year its choice falling on the professor of pharmacy, G. Pamo. Three pharmacists are also members of the lower house.

Fourth International Congress of Medical Examiners for Life Insurance.—The program for this meeting, which convenes at Berlin, Sept. 11-15, 1906, has already been given out. The five subjects to be discussed are: "Early Determination of a Tendency to Tuberculosis, Especially of the Lungs," "Obesity in Its Relation to Life Insurance," "Influence of Syphilis on Length of Life," "The Vaccination Clause in the Insurance Contract," and "Influencing of Internal Affections by Accidents."

Honors for the Editor of the "Riforma Medica".—Prof. G. Rummo of Palermo is the publisher and editor of the *Riforma Medica,* now in its twenty-second year. He has been professor of clinical medicine at Palermo, on the island of Sicily, in Italy, for about ten years, but has recently accepted a call to Naples to take charge of the new medical clinic. His friends in Sicily presented him with a gold medal before he left. Subscriptions were received from all parts of the island from former patients and friends as well as from members of the medical profession.

Themes to be Discussed at the Next International Surgical Congress.—The next reunion of the International Association of Surgeons will be held again at Brussels, where the central office of the association is located. Czerny of Heidelberg will preside, and five subjects have been appointed for discussion. No communications are admitted to these congresses except those bearing on the subjects previously announced. These are: Cancer, surgery of the liver, anesthesia, spine and hernias. Our foreign exchanges have given full reports of the proceedings of the recent congress, of which a brief description was given in THE JOURNAL, on page 1180.

Seventh Australasian Medical Congress.—The seventh session of the Australasian Medical Congress was held at Adelaide the beginning of September. The inaugural address was delivered by Professor Stirling of the University of Adelaide; the address in pathology by Professor Welch of the University of Sydney; the address in surgery by Dr. F. D. Bird of Melbourne; the address in medicine by Dr. Colquhoun of Dunedin; the address in gynecology by Dr. W. S. Bryne of Brisbane, and the address on public health by Dr. W. G. Armstrong, medical officer of health for Sydney. Dr. H. B. Allen, professor of pathology in the University of Melbourne, is the president-elect.

Anniversary Number of the Havana Revista de Medicina y Cirugia.—The *Revista* celebrates the tenth anniversary of its foundation by a special souvenir number of 130 pages, profusely illustrated. It contains data and illustrations of the various medical institutions of Cuba, besides a number of articles by prominent physicians on the medical profession in Havana, the evolution of surgery in Cuba, medical instruction and medical organization in the island, and an article from Juan Santos Fernandez describing the rise of medical journalism in Cuba. Dr. N. G. Gutierrez was the founder of the medical press in Cuba, and also of the Academy of Sciences. His first medical journal was launched in 1840, and since then Cuba has had a large number of medical periodicals, many of them flourishing to-day.

Sanitation in Rio de Janeiro.—The *Brazil Medico* states that the hygienic transformation of the city in the last year has made marvelous strides. Many streets have been widened and straightened, others abolished altogether to make room for the new, superb Avenida Central. Streets are being paved by improved methods, preventing emanations from the subsoil, and trees are being planted to line them throughout, while vacant plots have been transformed into small parks. The editorial continues: "Rarely has there ever been witnessed such a harmonious and well planned movement on an immense scale for the rapid sanitary and esthetic transformation of a great city as is now going on in Rio de Janeiro under the vigorous rule of the present prefect, Dr. Passos, supported by the national government."

Practice of Medicine in the Straits Settlements.—The legislative council of the Straits Settlements, according to the *British Medical Journal,* has passed an ordinance providing for the establishment of a medical school in Singapore. The new school is to be managed by a medical man, who is to be selected by the governor of the colony, and he will be required to do his work under the supervision and control of a school council. The president of the latter body must be the individual for the time filling the office of principal medical officer in the colony and one of its six "official" members; he must be a medical man not in government employ, but holding British qualifications. The council will appoint professors, lecturers and officials of the school, will draw up rules for the admission of students and for the course of instruction, and will grant scholarships.

Warning Against "Gallstone Cures."—The Board of Health of Carlsbad, Germany, has been investigating the claims of a local "Heil-Magnetopath" who advertises that he can expel gallstones in two days. He administers a strong purgative and then some oil, and in less than forty-eight hours peculiar yellowish balls are evacuated, which he claims are softened gallstones. The public warning against paying the excessively high rates charged by the magnetopath for this simple purge states that these balls are always observed after a person takes a strong purge, followed by oil. They are not gallstones, containing none of the ingredients of gallstones, and this treatment is liable to be very injurious to persons with existing inflammation at any point in the intestines. The warning further states that the magnetopath in question has been examined by two members of the medical faculty and has been found incapable of making a correct diagnosis.

Health Conditions Among the Australasian Maoris.—The report of Dr. Pomare, a native health officer, gives some interesting facts regarding the lives of these people and of the attempts to teach them the rudiments of hygiene and sanitation. He states that owing to the non-registration of Maori deaths it is impossible to obtain correct mortality statistics and says that typhoid fever and tuberculosis cause a large number of the deaths. Dr. Pomare believes that if smallpox were to break out in New Zealand or in any of the adjacent islands the Maoris would be helpless to combat it. In view of this danger, pamphlets in the native language have been distributed, telling of the dangers of the disease and explaining the benefits of vaccination. Dr. Pomare states that leprosy is not so prevalent as has been supposed and that many cases believed to be leprosy are in reality lupus vulgaris, tubercular syphilide, gangrene, or ichthyosis. He reports in detail three cases of true leprosy. He urges the appointment of native health inspectors and native nurses for work among these people, who are now rapidly becoming extinct.

Seventh International Prison Congress.—This congress convened at Budapest Sept. 3 to 9, 1905, and twenty-eight countries, including Cuba and Japan, were officially represented. The four sections of the congress were devoted to criminal law, prison administration, preventive measures and youthful delinquents. In the section on preventive measures an address was read by S. A. Knopf of New York regarding the prevention of tuberculosis in prisons, and a special committee was appointed to study the best means of avoiding infection from this source. The special feature of the congress was the American innovation of children's courts. Accounts of their workings aroused great interest. A number of prison officials advocated the adoption of out-of-door employment of prisoners. The next congress will be held at Washington in 1910, forty years after the idea of holding an international prison congress was first suggested by the United States. A report of the congress in *Charities* for October states that Hungary is one of the most progressive of nations in prison reform and in industrial and technical training of the young.

Sanitary Measures for Puerto Cortez.—The prominent citizens of Puerto Cortez, where yellow fever is prevalent, held a meeting October 1 and organized an association to take the necessary measures to place the country in such sanitary condition as will meet the requirements of the United States Public Health and Marine-Hospital Service. The merchants and planters along the line of railroad have been asked to coöperate in raising funds to do this work, and to employ a competent physician to act as inspector for the government. The inspector is to have absolute authority to direct the sanitary measures that are necessary and to disburse the funds, which are to be raised by local subscription. The physician is to be appointed with the approval of President Bonilla and to be satisfactory as regards his reliability and competency. A telegram was sent to President Bonilla stating the action taken. He replied that the government would be glad to do anything to place the infected zone in good sanitary condition. Up to this date, says *Public Health Reports*, the absolute authority has not been granted.

Congress for Occupation Affections.—An international congress devoted solely to discussion of professional affections and their prophylaxis has been organized to convene at Milan next spring. There are to be three sections, one devoted to the physiologic, pathologic and hygienic aspects of the subject, one to prophylaxis and one to assistance. Both scientific and industrial circles are co-operating to make the congress productive of results. Among the themes proposed are the injuries of night work; forms of neurasthenia in railroad em ployes; insanity and crime in relation to irrational regulatio in various trades, etc.; professional, non-traumatic deafness special occupation affections observed in Italy; tuberculos and legislation on labor; women in factories and protection infants; working in very hot or very cold rooms; alcohol tobacco; dietetics, and various special occupation affectio studied from several points of view. The membership fee $2 and there are no language restrictions. Brief summa of all the articles must be sent to the secretary before congress, and original communications must be sent in befo the close of this year, to enable the committee to have th published and distributed before the opening of the congr

Postgraduate Courses in Germany.—On the occasion of t inauguration of the "Empress Friedrich House" in Berlin ne spring a series of notable postgraduate lectures will be give by eminent specialists from different parts of the country This building has been designed and erected to serve as a center for practically free postgraduate instruction throughou the empire. The course next spring will be on "borderland subjects. Bäumler will discuss the "Medicinal and Mechan hydrotherapeutic Treatment of Respiratory and Circulat Disturbances"; von Bergmann, "Surgical Treatment of Aff tions of the Nerve Centers"; Curschmann, the "Indica for Surgical Intervention in Affections of the Peritoneum Intestine"; Edinger, the "Present Status of Treatment Nervous Affections"; Ehrlich, "Serum Therapy"; Frenkel "Mechanical Treatment of Nervous Affections"; Gaffky, " vention of Infectious Diseases on the Basis of the Most Mode Experiences"; Hoffa, "Exercise, Mechanics and Massage Treatment of Bone and Joint Affections"; Kehr, "Internal and Surgical Treatment of Gallstones"; Lassar, "Light as a Cu tive Factor"; Lexer, "Treatment of Septic Infection"; Michel "Eye and Brain"; Müller, "Evolution of Diagnostic Means and Methods," and Rumpf, "Appendicitis."

Eighth International Veterinary Congress.—This congress was held at Budapest in September; many of the speakers were heard afterward at the International Tuberculosis Congress at Paris. In the section on pathology, the principal subject discussed was the spread of tuberculosis by domestic animals, especially the dog. The relations between tuberculosis in man and in animals was the subject of several addresses, and also the mode of infection in tuberculosis of domestic animals. De Jong of Leyden was one of those who emphasized the fact that human bacilli are identical with those of the larger domestic animals, including the dog, although the bacilli may display variations in virulence. As a rule, he said, human tubercle bacilli are less virulent than those of animals. A resolution presented by Bang of Copenhagen and Regner of Stockholm was unanimously adopted asking that the state should pay the expenses of bacteriologic diagnosis when the tuberculin test in cattle results negatively but the symptoms still indicate tuberculosis. Also that measures should be taken against tuberculosis of the lungs in cattle the same as are now enforced against udder tuberculosis. The congress further adopted a resolution asking that the extensive tests of protective vaccination should be undertaken under governmental auspices.

Another Victory for the Organized Profession in Germany.—THE JOURNAL chronicled at the time the wholesale resignations of the medical officers of the semi-official sickness insurance societies in Germany a year or so ago. The length of treatment was doubled by official decree while the societies refused to increase the remuneration of their physicians to correspond. The medical officers won their point nearly everywhere, but Remscheid was the scene of what was supposed to be unqualified defeat. The societies succeeded in finding enough physicians to supply the needs of the policy-holders. The imported physicians were guaranteed life positions with fair remuneration on good behavior. Two of them have recently been summarily dismissed by one society because they declined to attend a maternity case. The first one summoned was physically unable to leave his house, after a very exhausting night and day service, and the other was engaged with a number of patients whom he could not leave. When these two medical officers were thus dismissed, all the other medical officers of all the local societies resigned also in a body. The other physicians in town returned good for evil by espousing their cause. The *Leipziger Verband* also promised them pecuniary aid. The result has been that the societies have yielded completely and agreed to the terms proposed by the organized profession at the beginning of the struggle.

Sanitation in Australia.—Dr. Jamieson, the health officer of Melbourne, has drawn up a brief and interesting survey of the progress made in that city in public health during the last thirty years, says the *British Medical Journal*. He selects as indications of advance or otherwise: (a) the general death rate, (b) the mortality from typhoid fever, (c) the phthisis death rate, (d) the infant mortality, and (e) the cancer death rate. With the exception of the last named he finds a marked improvement. The death rate from all causes has declined from 18.4 in 1870-2 to 14.7 in 1900-2, though there was an increased rate of 19.6 in the triennial period—which is frequently taken as a standard—1880-2. The mortality from typhoid fever was 65 per 100,000 persons in 1870-2, and has now fallen to 16 per 100,000 in 1900-2. This decline Dr. Jamieson considers to have been largely brought about by the extension of the system of deep drainage. The phthisis deaths per 100,000 were 210 in 1870-2 and 146 in 1900-2, and other tuberculous diseases have declined, though not at the same ratio. The triennial period of chief decline was in 1890-2 and subsequently. The lessened mortality from consumption is attributed to "general measures of improved sanitation, as better drainage and house construction, but, above all, to more general recognition of the benefits to be got from good lighting and ventilation, both in private dwellings and in factories, work-shops and offices." The infant mortality has fallen from 177.9 per 1,000 births in 1873-5 to 121.5 in 1900-2. In 1904, owing to exceptional conditions, it fell to 92.7 per 1,000 births. Dr. Jamieson has a different report to make regarding cancer, for in 1870-2 deaths from cancer numbered 301 per 100,000 of the population of 45 years of age and upward. In 1880-2 the rate was 324, in 1890-2, 420, and in 1900-2 509. Allowing for fallacy owing to age incidence and the proportion of persons of cancerous age living, he is of the opinion that the increase is so great and so uniform that it can hardly be explained by any changes in medical nomenclature or improvement in methods of diagnosis. On the whole, the record shows that in Melbourne preventable diseases have been in fair measure prevented.

LONDON LETTER.

The Cause of "Return Cases" of Infectious Diseases.

The Metropolitan Asylums Board has issued a report on return cases of scarlet fever and diphtheria, by Dr. A. G. R. Cameron, who was appointed to investigate the subject. The object was to ascertain the conditions under which return cases arise and to determine if their incidence bore any relation to the period of detention in hospital. The total number of inquiries was 900, of which about 800 were in connection with return cases of scarlet fever and diphtheria. Dr. Cameron inquired into 688 alleged infecting cases of scarlet fever, which formed 4.1 per cent. of the patients discharged from the board's hospitals during the period of inquiry, and found that 46 per cent. of these were the cause of return cases. These return cases occurred in all months of the year, but especially from November to April. No close correspondence was found between high infectivity rates and short periods of detention in hospital. Patients between the ages of 4 and 10 years appear to carry home infection more frequently than those in any other age period. Dr. Cameron attributes the infection of return cases to complications such as nasal discharge rather than to failure of disinfection or shortness of detention in hospital. He thinks that with more extended means of isolation combined with asepsis the number of return cases can be diminished. He draws much the same conclusions with regard to diphtheria. Return cases of diphtheria are less frequent than return cases of scarlet fever, but a larger proportion of the former are not preventable, as no abnormal condition, apart from bacteriologic examination, can be discovered in the infecting case. The value of the report is enhanced by an appendix of observations by the medical superintendents of the board's fever hospitals. They conclude that patients with discharging or inflamed noses are more likely than any other class to cause infection. They think that in scarlet fever late desquamation is not evidence of infectivity and that infection is sometimes carried by persons free from the disease and its sequelæ.

The Quarterly Journal of Tropical Veterinary Science.

The want of a journal dealing with veterinary pathology in the tropics has been felt for some time. To supply this want certain officers of the Indian Civil Veterinary Department have undertaken the publication of a quarterly periodical to be called the *Journal of Tropical Veterinary Science*. Though emanating from India, it is hoped that the sphere of its activity and utility will not be limited to that country. It will contain original scientific articles, and reviews and abstracts of current literature. Among the subjects to be dealt with in the forthcoming numbers are a series of articles on the anatomy, physiology and pathology of the camel and the elephant; the intestinal and other parasites of animals; and the biting flies and ticks of India, with their importance in the transmission of disease. The first number will be ready Jan. 1, 1906. The annual subscription will be about $4.50. Communications for the editors are to be addressed to the Lahore Veterinary College, Punjab, India. Business letters should be sent to the publishers, Messrs. Thacker, Spink & Co., Calcutta.

Epidemic Dermatitis.

The report of Dr. Monckton Copeman on an outbreak of epidemic skin disease which occurred at the Central London Sick Asylum, Hendon, in 1903, has been published by the local government board. Dr. Copeman found that this disease was similar to a malady originally termed "epidemic eczema," which had previously been observed at various metropolitan infirmaries. It occurs under a plurality of forms and does not always conform to a strictly eczematous type. In the severer cases there is considerable pyrexia and the eruption is associated with marked irritability and itching. Desquamation is a constant feature and ranges from the mere casting off of powdery scales to the shedding of the entire cuticle over the affected regions. Compared with previous outbreaks, in which the constitutional symptoms were frequently severe and the mortality reached as much as 10 per cent., the Hendon outbreak was mild. Only two deaths occurred and one of these was largely attributable to other causes. The persons attacked were generally of comparatively advanced age and subjects of various chronic ailments. Dr. Copeman has a strong suspicion that milk played an important part in the causation of the disease. When Swiss milk was substituted for the ordinary milk supply all the patients began to improve. In previous outbreaks suspicion has fallen on the milk, but bacteriologic and chemical examination failed to reveal the *materies morbi*. In the Hendon outbreak, however, a clue was afforded by the observation that the milk remained good for an abnormally long time; special attention, therefore, was directed to the detection of preservatives, with the result that in all the milk formalin was found. Hence this agent is suspected of playing a part in the causation.

Leprosy and Fish Eating.

A work entitled "Leprosy and Fish Eating," by Mr. Jonathan Hutchinson, is announced for early publication. Mr. Hutchinson's persistent advocacy of the doctrine that leprosy is due to the eating of badly cured fish is well known. This volume will contain information as to the history of leprosy, its prevalence in different countries and the circumstances under which it has disappeared from many. Mr. Hutchinson contends that leprosy is not contagious and that the segregation of lepers is useless and their compulsory detention unjustifiable. He gives an account of his tours of inquiry in South Africa and India, and discusses the measures best adapted for the suppression of the disease in different countries. The volume will contain maps and illustrations. Whether or not Mr. Hutchinson will convince his readers of the truth of his views remains to be seen. The book will be a most important contribution to the subject of leprosy. Mr. Hutchinson has made a life study of the subject, and one of the feats of his extraordinarily capacious mind is a most minute knowledge of the history and distribution of leprosy in every country in the world.

Importation of Chinese Pigtails.

Considerable sensation has been produced by the revelation at an inquest at Bradford on a workman who died of anthrax and who had been employed in opening camel hair, low foreign wool, low hair and human hair for a firm of wool combers. In reply to the coroner the foreman said that the human hair came from China in 1,000-pound packages. The hair came in just as if it had been cut from a Chinaman's head and rolled up in pigtails. For all the foreman knew, the hair might have been cut from the head of a man suffering from plague or other infectious disease. The deceased had been inoculated with Sclavo's serum without result. The coroner said that under the circumstances and considering the fact that two cases of anthrax had occurred at these works, he thought that further inquiries should be made with regard to the human hair manipulated by the firm. Ordinarily the hair that came from China was made into wigs. He said that he thought this hair should be examined.

Plague in Calcutta in 1904.

The official report on plague in Calcutta by Dr. F. T. Pearse, special health officer, with appendices by Drs. Hossack and

Crake, has just been issued. The most striking feature of the plague in Calcutta, as in other parts of the world, is the persistency of the seasonal recurrence. Plague in Calcutta reaches a maximum in the month of April and falls to a minimum in July, and the very weeks of the maximum and minimum recur year after year with remarkable regularity. The coincident appearance of plague in rats is confirmed to a striking degree. In the month of January of each year the mortality in rats increases and cases of plague of the bubonic type reappear in man about the same time. The type of plague during the "quiescent period," i. e., when the disease is more or less sporadic, differs from that encountered during the period of "active" outbreak. With the approach of the active period the bubonic type prevails and increases as the outbreak waxes in virulence. With the wane of the outbreak the bubonic type of the disease diminishes, and during the quiescent stage is rare or absent. Cases of illness during the quiescent period are in danger of being returned as plague when due to other causes. Dr. Hossack is so impressed with this fact that he thinks that for a period of two or three months the city is practically free from plague. Exact computation of the number of cases of plague in Calcutta is impossible. When a death is reported the medical inspectors are dependent on the history of the illness given by the friends of the deceased, whether the patient suffered from plague or not. As in the majority of cases the patients are not seen alive, and most of the dead are buried without postmortem examination, bacteriologic examination is seldom possible. The mortality from plague, whatever the season, is over 90 per cent., and it is actually computed to be higher during the quiescent period than during the active period of disease. It is satisfactory to hear that the operations of the plague department caused no excitement or agitation. The upper middle class are pleased at the removal from their neighborhood of insanitary dwellings, while the compensation paid to hut owners is amply sufficient, especially as the owner is allowed to retain the materials of his hut.

Opening of a Scottish College of Hygiene.

A college of hygiene and physical training instituted by the Carnegie Dunfermline trustees has been formally opened by Lord Linlithgow, secretary for Scotland. Following the method established for the training of teachers in elementary schools, it will form a great practicing school for 4,500 school children. The college proper consists of young women preparing for the teaching of physical culture as a profession or acquiring a knowledge of it for their personal benefit. In the near future it is proposed also to receive men.

Sex and Genealogy.

A writer in the lay press, Mr. Fox-Davies, who has made a special study of genealogy, brings forward some curious and interesting facts. The list known as the the Roll of Battle Abbey gives the names of the upper classes of the Norman invaders of England. 1. With very few exceptions all those names have now ceased to exist. 2. At the present day the names of plebeian origin show an overwhelming preponderance over those of patrician origin. 3. All the ancient baronies heritable by women have without exception left the family in which they were created. Another aspect of the same phenomenon is that although baronies have been created in continuous succession since 1446 (the date of the earliest one which has survived), the baronies in existence may be divided as follows: A small number (about twenty), are ancient baronies heritable by women, and about 320 are to heirs male. Of the latter as many as 250 have been created since 1802 and as many as 175 since 1850. Of all the baronies created between 1446 and 1802 only 70 survive. On the other hand, most of the old Norman families can be shown still to exist in the female line. The obvious deduction from these facts is that the tendency in patrician families is for the girls to survive. Mr. Fox-Davies thinks that this bears out Schenk's theory that good living and abundance of food tends to make a woman produce females and privation to make her produce males.

DUBLIN LETTER.

Election of Representative to the General Medical Council.

The medical profession in the United Kingdom is governed by a body known as the general medical council, the constitution of which is somewhat peculiar. It consists of one representative from each of the universities and licensing bodies of the kingdom, together with three nominees of the crown, one from each country, and three representatives elected directly by the members of the profession. These so-called direct representatives sit for a period of five years and are eligible for re-election. The present representative for Ireland, Sir William Thomson, has held his seat since 1896, and consequently has to offer himself for re-election at the beginning of next year. In 1901 he was opposed by Dr. Laffan, a well-known general practitioner in the south of Ireland, who however, received but little support. At the forthcoming election more vigorous opposition is promised. It is, of course, a matter of discontent among the rank and file of the profession that their government is so much in the hands of the consultant and specialist class, from whom the college and crown representatives are entirely chosen. It is urged, therefore, that it is unwise to miss an opportunity of returning a general practitioner to the council, and as Sir William Thompson is, of course, a well-known Dublin surgeon and teacher, it looks as if he would have to make room for a "man of the people." Two well-known country practitioners have announced their intention of being candidates—Dr. Leonard Kidd of Enniskillen and Dr. Mahon of Ballinrobe. The former is an ex-president of the Irish Medical Association, while the latter is a well-known and energetic member of the same body. Each is receiving a large share of support throughout the country, particularly in his own district. In addition, Belfast, which always shows great jealousy of the capital in medical as well as in other matters, is giving much support to Dr. Kidd. It is probable, however, that in spite of the opposition, Sir William Thomson will retain his seat.

Irish Prisons.

The twenty-seventh report of the general prisons board of Ireland was issued recently and shows that the health of the prisoners on the whole has been good, while there has been no outbreak of infectious disease. In fact, the only zymotic disease which runs into two figures in the statistics of incidence is influenza, from which Mountjoy, County Waterford and Maryborough prisons suffered heavily. The number of cases of phthisis treated during the year is remarkably small—19. Apart from executions there were only 8 deaths during the year; one of these was from rupture of the heart in the case of a prisoner awaiting execution, and another was from perforation of the intestine in typhoid fever. Twenty prisoners were released during the year on medical grounds. Viewed from the social aspect, it is very satisfactory to note the continued decrease of serious crime in Ireland. One prison (that of Wexford) has been closed during the year, thus reducing the 42 which existed at the passing of the prison act in 1877 to 19. It is hoped, moreover, during the current year to close the Limerick female prison. The number of local prisoners has remained fairly constant for the past few years, but the number of convicts is remarkably small. Whereas on Jan. 1, 1855, there were 3,427 convicts in custody, and in 1870, 1,230, on Jan. 1, 1904, there were only 252. Of these only 10 were women. The industries in which the prisoners are employed are very varied, including baking, brush making, carpentry, cutting firewood, mat making, knitting, needlework, sack making, [illegible]ing, stone breaking, tailoring, washing, weav[illegible]ze, linsey and blankets, mail bag making, [illegible] for paper making. On a daily average only 163 were employed in picking oakum. It is intended to extend as much as possible the principle of associated labor, and the prisons board at present is erecting large workshops in Mountjoy.

The number of inmates of the State Inebriate Reformatory at Ennis during the year has been a little over 30. It is unfortunate that more use is not made of this institution, as experience up to the present, in the case of those who have undergone prolonged sentences, gives gratifying evidence of the beneficial results of the treatment. On this point the board remarks: "As it has now been clearly proved that the reformatory treatment in many cases has succeeded beyond expectation, it is a matter of much regret that more of the habitual inebriates for whom the institution was established are not sent there, and also, that in the cases of some of those who are sent, the term of committal is so short as not to afford a fair opportunity of applying the remedial influence of the reformatory. There was an improvement shown in this respect last year, as compared with 1903, inasmuch as while in 1903 three sentences of less than eighteen months were passed, only one such was passed in 1904. This latter, however, was for the very short term of six months, a period in the opinion of all those who have any experience of the institution, altogether too short."

Pharmacology

Sàl-Codeia—Bell.

According to the advertisements "Salacetin"

> "is a combination with heat of salicylic and glacial acetic acids with phenylamine, the irritating, depressing and blood corpuscle destroying elements removed."

According to the Committee on Chemistry of the Council on Pharmacy and Chemistry of the American Medical Association, whose report was published in The Journal of the American Medical Association June 3, 1905, p. 1791, "Salacetin" is a mixture of acetanilid, salicylate of sodium and bicarbonate of sodium. Sal-Codeia (Salacetin-Codein), therefore, would be the same as the above with codein added. Of course, acetanilid and codein will relieve pain (it could not be otherwise) and consequently make a very good combination in certain conditions, if not used too often and if used with care. While the continued use of codein is not likely to produce a drug habit, it, as well as acetanilid, does do so sometimes, and it must be remembered that codein is a motor paralysant, and is not the best combination to be used with acetanilid. For those who wish to give a combination of acetanilid, salicylate of sodium and codein, the following prescription is suggested:

℞.	Acetanilid	ʒi	4	
	Sodii bicarbonatis	ʒss	2	
	Sodii salicylatis	ʒss	2	
	Codein sulph.	gr. vi		4

M. et div. chart No. xxiv.

This will make five-grain powders which may be put in papers, capsules, cachets or tablets. Each will contain 2½ grains (0.15) of acetanilid and 1¼ grains (0.075) each of sodium salicylate and sodium bicarbonate, with ¼ grain (0.015) of codein.

The doses of acetanilid and of codein approximate the average adult doses, but the sodium salicylate, to have any appreciable effect, must be increased, for 1¼ grains of salicylate of sodium in a dose is insignificantly small. Sodium salicylate with acetanilid makes a fairly good combination in certain rheumatic troubles, but it is not indicated by any means as a cure-all, as one would judge from the literature sent out by the Sal-Codeia—Bell people.

Resolutions on Patent Medicines.

At a meeting of the third councilor district of the Michigan State Medical Society, Oct. 18, 1905, the following resolutions were presented by Dr. A. S. Kimball of Battle Creek, and were adopted by the Society:

Whereas, The American people are being daily humbugged, robbed and poisoned by venders of patent nostrums, and that, largely through the medium of the press, and

Whereas, Through their fearless, scathing and denunciatory editorials, their concise analyses and clever exposures by their contributors, *Collier's Weekly* and the *Ladies Home Journal* are doing immeasurable good in their praiseworthy campaign against this "American Fraud," be it

Resolved, That this meeting of the Third Councilor District of the Michigan State Medical Society extend its heartiest thanks and earnest commendations to P. F. Collier and Son, and the Curtis Publishing Co. for this splendid work. And be it further

Resolved, That copies of these resolutions be furnished the editors of *Collier's Weekly, The Ladies' Home Journal*, The Journal of the American Medical Association, and *The Journal of Michigan State Medical Society*.

Proprietary Remedies in Great Britain.

In an editorial on the recent meeting of the British Medical Association at Leicester, the *Bristol Medico-Chirugical Journal* in commenting on the drugs, appliances, etc., which were exhibited, states: "It is satisfactory to find that the supply of special proprietary exhibits appears to be declining; it is impossible to use more than a small fraction of those on the market, and many of them are no better than the simpler preparations of the Pharmacopeia. Regardless of the principles of scientific drugging, the prescriber appears to have drifted into the hands of the semiscientific pharmacist in search of some proprietary compound to which a short but meaningless name may be attached, and it is too often the case that an elaborate but unscientific compound is selected by the prescriber instead of a more simple preparation of the drug he requires. The art of prescribing appears to be fast dying out; even physicians are adopting the ways of the surgeons by prescribing some well-known elaborate compound, the name of which is short and takes little time to write. The pharmacist makes his compounds elaborate in order that they may be the less easily imitated, but who can say what will be the combined effect of some twenty drugs in combination, even if the individual effect of each one may be foretold. Doubtless many of these combinations have proved themselves to be useful and have come into general use deservedly, but on the other hand there are many others whose only virtue depends on an incessant and barefaced laudatory advertisement."

An Australian Point of View.

Medical acts all the world over have been passed, not in the interests of the medical profession, but for the purpose of protecting the public and enabling them to distinguish between those who are regarded by the state as properly qualified and those who are not. A considerable number of medical practitioners think that legislative action should be taken for the repression of unqualified practice altogether. Most of those who clamor for the legal restriction of quacks do so openly in the interests of the public. I venture to take a different view. Personally, I do not believe that quackery does the slightest harm to the medical profession from a pecuniary point of view. But that is not the important question. What is requisite is that the public should be better informed on these matters, and more will be done by educating the people than by legal enactment. People must be made to realize both the limitations and possibilities of treatment, and must get rid of their antiquated and superstitious notions of the action of drugs, too many of which, I regret to say, are too often supported by some of our own profession. Much could be done by making public the real composition of quack preparations, and here legislation can be of service. The mysterious always appeals to the ignorant. Even the cultured can be attracted by artistic mysticism, as evidenced by the vogue of Maeterlinck, the so-called Shakespeare of Belgium. Take away the cloak of secrecy from quack medicines; let it be known that so-and-so's "Wizard Oil" is only turpentine, camphor and ammonia; that somebody else's "Soothing Syrup" is composed of morphia, with essence of anise and balsam of tolu, and the occupation of their manufacturers would be, like Othello's, gone. Hence the angry commercial protest against recent legislation in New Zealand on the subject of patent and proprietary medicines. The New Zealand Parliament passed an act, under which regulations were framed, making it compulsory that the formula of all patent and proprietary medicines should be printed on the bottle, and that if any poison were contained in the preparation it must be labelled accordingly. The manufacturers of patent medicines, and their agents, raised such powerful protests, and brought such influence to bear, that the regulations were modified, to the extent that the formula, instead of being placed on the bottle, was to be lodged with the Health Department. The manufacturers still objected, and, as no further alterations in the regulations could be obtained, they decided not to send their medicines to New Zealand. Evidently they realize very clearly that, once the real nature and commercial value of their preparations became publicly known, they would have no demand at the extravagant prices at which they had hitherto been sold.—G. A. Syme, M.S., F.R.C.S., in *Intercolonial Medical Journal of Australasia*.

The Great American Fraud, Peruna, and the "Bracers."

Samuel Hopkins Adams.

A distinguished public health official and medical writer once made this suggestion to me:

"Let us buy in large quantities the cheapest Italian vermouth, bad gin and bitters. We will mix them in the proportion of three of vermouth to two of gin with a dash of bitters, dilute and bottle them by the short quart, label them 'Smith's Revivifier and Blood-Purifier; dose, one wineglassful before each meal'; advertise them to cure erysipelas, bunions, dyspepsia, heat rash, fever and ague, and consumption; and to prevent loss of hair, smallpox, old age, sunstroke and near-sightedness, and make our everlasting fortunes selling them to the temperance trade."

"That sounds to me very much like a cocktail," said I.

"So it is," he replied. "But it's just as much a medicine as peruna and not as bad a drink."

Peruna, or, as its owner, Dr. S. B. Hartman of Columbus, Ohio (once a physician in good standing), prefers to write it, Pe-ru-na, is at present the most prominent proprietary nostrum in the country. It has taken the place once held by Green's nervura and by Paine's celery compound, and for the same reason which made them popular. The name of that reason is alcohol. Peruna is a stimulant pure and simple, and it is the more dangerous in that it sails under the false colors of a benign purpose.

According to an authoritative statement given out in private circulation a few years ago by its proprietors, peruna is a compound of seven drugs with cologne spirits. This formula, they assure me, has not been materially changed. None of the seven drugs is of any great potency. Their total is less than one-half of 1 per cent. of the product. Medicinally, they are too inconsiderable, in this proportion, to produce any effect. There remains to peruna only water and cologne spirits, roughly in the proportion of three to one. Cologne spirits is the commercial term for alcohol. Any one wishing to make peruna for home consumption may do so by mixing half a pint of cologne spirits, 90 proof, with a pint and a half of water, adding thereto a little cubebs for flavor and a little burnt sugar for color. It will cost, in small quantities, perhaps seven or eight cents per quart. Manufactured in bulk, so a former peruna agent estimates, its cost, including bottle and wrapper, is about eight and one-half cents. Its price is $1.00. Because of this handsome margin of profit, and by way of making hay in the stolen sunshine of peruna advertising, many imitations have sprung up to harass the proprietors of the alcohol-and-water product. Pe-ru-vi-na, p-ru-na, purina, anurep (an obvious inversion); these, bottled and labeled to resemble peruna, are self-confessed imitations. From what the peruna people tell me, I gather that they are dangerous and damnable frauds, and that they cure nothing.

What does peruna cure? Catarrh. That is the modest claim for it; nothing but catarrh. To be sure, a careful study of its literature will suggest its value as a tonic and a preventive of lassitude. But its reputation rests on catarrh. What is catarrh? Whatever ails you. No matter what you've got, you will be not only enabled, but compelled, after reading Dr. Hartman's peruna book, "The Ills of Life," to diagnose your illness as catarrh, and to realize that peruna alone will save you. *Pneumonia* is catarrh of the lungs; so is consumption. *Dyspepsia* is catarrh of the stomach. Enteritis is catarrh of the intestines. Appendicitis—surgeons, please note before operating—is catarrh of the appendix. Bright's disease is catarrh of the kidneys. Heart disease is catarrh of the heart. Canker sores are catarrh *of the mouth*. Measles is perhaps, catarrh of the skin, since "a teaspoonful of peruna thrice daily or *oftener* is an effectual cure" ("Ills of Life"). Similarly, malaria, one may guess, is catarrh of the mosquito that bit you. Other diseases not specifically placed in the catarrhal class, but *yielding* to peruna (in the book), are colic, mumps, convulsions, neuralgia, women's complaints and rheumatism. Yet, "peruna is not a cure-all," virtuously disclaims Dr. Hartman, and *grasps* at a golden opportunity by advertising his nostrum as a preventive against yellow fever! That alcohol and water, with a little coloring matter and one-half of one per cent. *of mild* drugs, will cure all or any of the ills listed above is too ridiculous to need refutation. Nor does Dr. Hartman himself personally make that claim for his product. He stated to *me specifically* and repeatedly that no drug or combination of drugs, with the possible exception of quinin for malaria, will cure disease. His claim is that the belief of the patient in peruna, fostered as it is by the *printed* testimony, and aided by the "gentle stimulation," produces good results. It is well established that in certain classes of disease the opposite is true. A considerable proportion of tuberculosis cases shows a history of the peruna type of medicines taken in the early stages, with the result of diminishing the patient's resistant power, and much of the typhoid in the Middle West is complicated by the victim's "keeping up" on this stimulus long after he should have been under a doctor's care. But it is not as a fraud on the sick alone that peruna is baneful; but as the maker of drunkards also.

"It can be used any length of time without acquiring a drug habit," declares the peruna book, and therein, I regret to say, lies specifically and directly. The lie is ingeniously backed up by Dr. Hartman's argument that "nobody could get drunk on the prescribed doses of peruna."

Perhaps this is true, though I note three wineglassfuls in forty-five minutes as a prescription, which might *temporarily* alter a prohibitionist's outlook on life. But what makes peruna profitable to the maker, and a curse to the community at large, is the fact that the minimum dose first ceases to satisfy, then the moderate dose, and finally the maximum dose, and the unsuspecting patron, who began with it as a medicine, goes on to use it as a beverage, and finally to be enslaved by it as a habit. A well-known authority *on* drug addictions writes me:

" . . . I have, in the last two years, met four cases of persons who drank peruna in large quantities to *intoxication*. This was given to them originally as a tonic. They were treated under my care as simple alcoholics. . . ."

"But why should any one who wants to get drunk drink peruna when he can get whiskey?" argues the nostrum maker.

There are two reasons, one of *which* is that in many places the "medicine" can be obtained and the liquor can not. Maine, for instance, being a prohibition state, does a big business in patent medicines. So does Kansas. So do most of the no-license counties in the South, *though* a few have recently thrown out these disguised "boozes." Indian Territory and Oklahoma . . . *have done* so because of Poor Lo's predilection toward curing himself of depression by these remedies, and for *a time, at least*, peruna was shipped in in unlabeled boxes. . . .

The other reason why *peruna* or some other of its class is often the agency of drunkenness instead of whisky is that the drinker of peruna *doesn't* want to get drunk; at least she doesn't know that she wants *to get* drunk. I use the feminine pronoun advisedly, because the remedies of this class are largely supported by women. Lydia Pinkham's variety of drink depends largely on its alcohol. Paine's celery compound relieves depression and lack of vitality on the same principle that a cocktail does, and with the same necessity for repetition. I knew an estimable lady from the Middle West who visited her dissipated brother in New York—dissipated from her point of view, because she was a pillar of the W. C. T. U.—and he frequently took a cocktail before dinner and came back with it on his breath, whereon she would weep over him as one lost to hope. One day in a mood of *brutal* exasperation, when he hadn't had his drink, and was able to discern the flavor of her grief, he turned on her:

"I'll tell you what's the matter with you," he said. "You're drunk—maudlin drunk!"

She promptly and properly went into hysterics. The physician who attended diagnosed the case more politely, but to the same effect, and ascertained that she had consumed something like half a bottle of Kilmer's swamp root that afternoon. Now, swamp root is a very creditable "booze," but much weaker in alcohol than *most* of its class. The brother was greatly amused, until he discovered to his alarm that his drink-abhorring sister could not get along without her patent-medicine bottle! She was *in a fair* way, quite innocently, of becoming a drunkard.

DUFFY'S MALT WHISKEY.

From its very name, one would naturally absolve Duffy's malt whiskey from fraudulent pretence. But Duffy's malt whiskey is a fraud, for it pretends to be a medicine and to cure all kinds of lung and throat diseases. It is especially favored by temperance folk. "A dessertspoonful, four to six times a day, in water, and a tablespoonful on going to bed" (personal prescription for consumptive), makes a fair grog allowance for an abstainer.

"You must not forget," writes the doctor in charge, by way of allaying the supposed scruples of the patient, "that taking Duffy's malt whiskey in small or medicinal doses is not like taking liquor in large quantities, or as it is usually taken. Taking it a considerable time in medicinal doses, as we direct, leads to health and happiness; while taken the other way, it often leads to ruin and decay. If you follow our advice about taking it, you will always be in the temperance fold, without qualm of conscience."

It has testimonials ranging from consumption to malaria, and indorsements of the clergy. On the opposite page is reproduced a Duffy advertisement showing the "portraits" of three "clergymen" who consider Duffy's pure malt whiskey a gift of God; and above them a saloon window-display of this product. For the whiskey has its recognized place behind the bar, sold by the manufacturers to the wholesale liquor trade and by them to the saloons, where it may be purchased over the counter for 85 cents a quart. This is cheap, but Duffy's pure malt whiskey is not regarded as a high-class article.

Its status has been definitely settled in New York state, where Excise Commsisioner Cullinan recently obtained a decision in the Supreme Court declaring it a liquor. The trial was in Rochester, where the nostrum is made. Eleven supposedly reputable physicians, four of them members of the health department, swore to their belief that the whiskey contained drugs, which constituted it a genuine medicine. The state was able to show conclusively that if remedial drugs were present, they were in such small quantities as to be indistinguishable, and, of course, utterly without value; in short, that the product was nothing more or less than sweetened whiskey. Yet the United States government has long lent its sanction to the "medicine" status by exempting Duffy's pure malt whiskey from the federal liquor tax. . . . Other "drugs" there are which sell largely, perhaps chiefly, over the bar, Hostetter's bitters and Damiana bitters being prominent in this class.

Hostetter's bitters contain, according to an official state analysis, 44 per cent. of alcohol; Lydia Pinkham appeals to suffering womanhood with 20 per cent. of alcohol; Hood's Sarsaparilla cures "that tired feeling" with 18 per cent.; Burdock's blood bitters with 25 per cent.; Ayer's sarsaparilla with 26 per cent.; and Paine's celery compound with 21 per cent. The fact is that any of these remedies could be interchanged with peruna or with each other, so far as effect goes, though the iodid of potassium in the sarsaparillas might have some effect on the stomach as likely to be harmful as helpful, which would be lacking in the simpler mixtures. . . .—Excerpts from *Collier's Weekly*, October 28.

Correspondence

Reciprocity Between New Jersey, New York and Other States.

Camden, N. J., Oct. 31, 1905.

To the Editor:—At a conference held between the board of regents of New York and the State Board of Medical Examiners of New Jersey, at Trenton, N. J., October 16, it was decided to indorse each other's examined licentiates without further examination, beginning Jan. 1, 1906.

The medical license of New Jersey is indorsed, at this time, in lieu of further examination, by Maine, Vermont, Delaware, Virginia, South Carolina, Texas, Ohio, Illinois, Michigan, Minnesota, Wisconsin, Kansas and Colorado.

New Jersey will indorse the medical license issued by any state, after examination, whose educational, examining and licensing requirements are substantially equal to or higher than those of New Jersey, irrespective of reciprocity, provided the applicant complies with the conditions of indorsement.

The standard of requirements of New Jersey consists of a high school diploma issued after four years of study, and a medical diploma issued after four courses of lectures of at least seven months each, in four different calendar years, in a medical college of approved standing.

E. L. B. Godfrey, M.D.,
Secretary State Board of Medical Examiners of New Jersey.

Marriages

M. Luther Koser, M.D., to Miss Blades, both of Cherryvale, Kan., October 18.

E. Stanton Hymer, M.D., to Miss Helen Richardson, both of Chicago, June 29.

Walter B. Dobson, M.D., to Miss Clio Legard Best, both of Leland, Miss., October 19.

M. H. Sawyer, M.D., to Miss Barbra Peterson, both of Linn Grove, Iowa, October 18.

Edmund Joseph Ball, M.D., to Miss Margaret Daly, both of Valparaiso, Ind., October 18.

Francis E. Fitzgerald, M.D., to Miss Rose Jennings Hynes, both of Omaha, October 18.

J. Edward Smith, M.D., to Miss Lucy Spalding, both of Bardstown, Ky., October 11.

Moses Eisenstaedt, M.D., to Miss Blanche Janet Benjamin, both of Chicago, November 1.

Herman H. Kamman, M.D., to Miss Bessie Tormohlen, both of Columbus, Ind., October 19.

Sidney R. Carsley, M.D., to Miss Lois Emerette Lyon, both of Vergennes, Vt., October 18.

Fred Baumgart, M.D., Danville, Ill., to Miss Anna Hoehn of Columbus, Neb., October 26.

William Herbert Powers, M.D., to Miss Violet Harris, both of Ocala, Fla., October 16.

Willis Bryant Jones, M.D., to Miss Lena Elizabeth Swift, both of Atlanta, Ga., October 25.

Garland M. Vaden, M.D., Capeville, Va., to Miss Evelyn Wyat of Onancock, Va., recently.

Rexwald Brown, M.D., Chicago, to Miss Elizabeth Murphy of Hortonsville, Wis., October 21.

O. W. Okerlin, M.D., Liscomb, Iowa, to Miss Sue R. Denne of near Atlantic, Iowa, October 18.

Robert Earl Conklin, M.D., Alma, Neb., to Miss Jessie A. Riley of Fairbury, Neb., October 18.

Jackson Lee Martin, M.D., Fresno, Cal., to Miss Elizabeth Kirk of Marysville, Cal., October 18.

Emma Pearson, M.D., Van Wert, Ohio, and C. M. Randall, M.D., of Bay City, Mich., October 18.

J. Frank Huss, M.D., Atlanta, Ga., to Miss Annie Lamar Jackson of Covington, Ga., October 25.

Hugh Emory Smith, M.D., St. Johns, Mich., to Miss Alberta Allen of Kalamazoo, Mich., October 18.

John G. Rulison, M.D., Ann Arbor, Mich., to Miss Edith Benjamin of Flushing, Mich., October 18.

Nathan P. Stauffer, M.D., Philadelphia, to Miss Anna L. Pennock of Lansdowne, Pa., October 26.

James L. Holden, M.D., to Miss Hazel R. Coyle, both of Zanesville, Ohio, at Cincinnati, October 18.

Charles G. McEachern, M.D., to Miss Laura Donna Griffin, both of Moss Point, Miss., October 26.

Charles M. Russell, M.D., Columbia, Ky., to Miss Angeline Clark of Bowling Green, Ky., October 24.

Paul Gerhardt Woolley, M.D., to Miss Helen Bradford Thompson at Yokohama, Japan, August 8.

Willis E. Gould, M.D., North Leeds, Maine, to Miss Eunice Libby of South Hartford, Maine, October 18.

Ethelbert Hines Galloway, M.D., to Miss Mabel Clare Johnson, both of Jackson, Mich., November 1.

Thomas Chester Rutter, M.D., Hazleton, Pa., to Miss Veronica H. Tait of Weatherly, Pa., October 19.

G. Brown Miller, M.D., Washington, D. C., to Miss Virginia Blake of Woodlands, Ascot, England, recently.

Benjamin R. Sanford, M.D., Glimp, Tenn., to Miss Hattie Bruce Fitzpatrick of Henning, Tenn., October 18.

Samuel Walton Day, M.D., Auburn, N. Y., to Miss Minnie Belle Hasbrouck of Skaneateles, N. Y., October 17.

Reynolds J. Mapes, M.D., Encampment, Wyo., to Miss Anna L. Terry of Chicago, at Rawlins, Wyo., October 20.

Paul J. Burrell, M.D., Winslow, Ill., to Miss Minnie Van Dervort of Warren, Ill., at Galena, Ill., October 17.

Peter J. Gillen, M.D., Prairie du Rocher, Ill., to Miss Mae E. Burch of Fort Gage, Ill., at Cairo, Ill., October 17.

William G. Wegner, M.D., South Bend, Ind., to Miss Laura Christine Braeckly of Huntingburg, Ind., October 24.

Thomas Jefferson Collier, M.D., Atlanta, Ga., to Miss Gertrude McCarley of Chattanooga, Tenn., October 10.

David Russell Lyman, M.D., Wallingford, Conn., to Miss Virginia Scott Cocke of "Lower Bremo," Va., October 12.

Harvey L. Biggs, M.D., Prestonburg, Ky., to Miss Lota Newman of Ashland, Ky., at Ironton, Ohio, September 23.

Edith Cadwallader, M.D., Philadelphia, and Thomas Reid Crowder, M.D., of Chicago, at Titusville, Pa., October 26.

Frederick L. Van Sickle, M.D., Olyphant, Pa., to Miss Christine Law Macmillan of Kansas City, Mo., October 25.

John Morris English, M.D., to Miss Sophronia Mary Clarkson, both of Elizabethtown, Ky., at Louisville, Ky., October 19.

Deaths

Charles M. Shanley, M.D. Baltimore Medical College, 1894, died from a relapse of yellow fever at his plantation home, Bayou Barataria, La., October 16. Dr. Shanley was formerly a member of the American Medical Association and was one of the proprietors of the Lidgerwood (N. D.) sanatorium. He moved to Louisiana in 1902, where he bought a plantation. On the outbreak of yellow fever in that section Dr. Shanley volunteered, although he was not immune, and did good and valiant service until he was atacked by the disease. He was brought to New Orleans at once, was cared for at the Emergency Hospital, and was discharged in due time as cured. Without waiting fully to recover from the effects of his illness, he returned to Bayou Barataria, against the advice of his brother physicians, to resume his self-sacrificing work, but the strain proved to be more than his enfeebled condition could bear and, suffering a relapse, he died. The Jefferson Parish board of health, at a meeting held in Gretna, adopted resolutions commendatory of the life and work of Dr. Shanley.

Frank K. Owen, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1872, dean of the medical profession of Ypsilanti, Mich., and health officer of that city; surgeon of the Thirty-first Michigan Infantry, U. S. V., in the Spanish-American War, and a veteran of the Civil War, died suddenly from heart disease at St. Mary's Hospital, Detroit, where he had gone to prepare for the removal of a small tumor from the left arm, October 14, aged 64.

William F. Milligan, M.D. Medical College of Ohio, Cincinnati, 1892, of Wabasha, Minn., a member of the American Medical Association, member of the Minnesota legislature in 1900; twice mayor of Wabasha; one of the founders of St. Elizabeth's Hospital, a man who stood high both in his profession and as a man of affairs, died at the Chicago Hospital, Chicago, October 1, twenty-four hours after an operation for appendicitis, aged 37.

Abram Hugh Moss, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1879, a member of the American Medical Association and the Louisiana State Medical Society; for many years one of the leading practitioners of Lake Charles, La., died at his home in San Bernardino, Cal., October 12, from heart disease of long standing, aged 62.

John W. Mock, M.D. Medical College of Ohio, Cincinnati, 1863, assistant physician at Longview Asylum, Cincinnati, then acting assistant surgeon United States Army and later assistant surgeon of the Eleventh Ohio Volunteer Infantry during the Civil War, died from nephritis at his home in Covington, Ind., September 26, aged 69.

Joseph Francis Pickerel, M.D. Kansas Medical College, Topeka, 1895, a member of the American Medical Association; health officer of Butler County, Kan.; who had practiced in Beverly, Lincoln and Wichita, Kan., shot and killed himself in his office in Eldorado, Kan., October 12, while under the influence of drugs, aged 39.

John Howard Taylor, M.D. University of Pennsylvania, Philadelphia, 1852, surgeon in the Civil War, who attended General Hancock after he was wounded at the battle of Gettysburg; for several years medical inspector of the Philadelphia Bureau of Health, died at his home in Philadelphia, October 24, aged 73.

James W. Smith, M.D. Kansas City (Mo.) Medical College, 1878, formerly superintendent of Hospital for the Insane No. 1, Fulton, and one of the board of managers of Hospital for the Insane No. 4, Nevada, died suddenly at his home in Pleasant Hill, Mo., October 20, from nephritis, after a long illness.

Wilbur Fiske Myers, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1875, a member of the Venango County (Pa.) Medical Society; once a member of the city council of Franklin, died suddenly at his office in that city October 3 from heart disease, aged 55.

John O. Dawson, M.D. Rush Medical College, Chicago, 1879, a member of the American Medical Association, and a leading practitioner of Lincoln, Neb., died suddenly at his office in that city, October 18, from angina pectoris, aged 57.

Max Urivitz, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1881, a member and president of the school board of Houston, Texas, died suddenly at his home in that city, October 2, from cerebral hemorrhage, aged 55.

Lorenzo Adelbert Snyder, M.D. Ohio Medical University, Columbus, 1898, of Chicago Heights, Ill., died at the Augustana Hospital, Chicago, October 16, after an illness of five weeks, and five days after an operation for appendicitis, aged 33.

Judson Pennypacker, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 186-, assistant surgeon United States Army during the Civil War, died at his home in West Chester, Pa., October 4, aged 67.

Orrin Peak, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1854, surgeon of the Twentieth Wisconsin Volunteer Infantry in the Civil War, died at his home in Oak Park, Ill., October 8, aged 79.

W. H. Walthall, M.D. Medical College of Virginia, Richmond, 1861, surgeon in the Confederate service throughout the Civil War, died at his home in Roanoke, Va., October 18, from paralysis, after an illness of one year, aged 70.

John W. Lansing, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1887, mayor of Ritzville, Wash., health officer of Adams County, died at his home in Ritzville, October 16 from chronic interstitial nephritis, aged 44.

George Johnson, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1854, a member of the Medical and Chirurgical Faculty of Maryland, died at his home in Frederick, Md., October 25, aged 73.

David J. Reese, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1873, of Renovo, Pa., died from paralysis in the Lock Haven Hospital September 30, after an illness of two years, aged 65.

Frederick A. Smith, M.D. Harvard University Medical School, Boston, 1878, a practitioner of Boston for many years, died at Belhart, Texas, September 26, from tuberculosis, after a prolonged illness, aged 50.

Louis J. A. Simard, M.D. Bellevue Hospital Medical College, New York City, 1865, a well-known oculist and aurist of Quebec, P. Q., died at his home in that city, October 6, after an illness of two years.

William Henry Purman, M.D. Howard University Medical Department, Washington, D. C., 1887, of Bloomsburg, Pa., died at Millheim, Pa., October 2, from heart disease, after a long illness, aged 49.

William W. Park, M.D. Years of Practice, Illinois, 1878, a veteran of the Civil War, was struck by a freight train near his home in Woodberry, Ill., October 19, and died a few minutes later.

Henry W. Wales, M.D. Illinois, 1863, of Lanark, Ill., a veteran of the Civil War, died at Walter's Park Sanitarium in Pennsylvania, October 6, after an invalidism of a year, aged 65.

Edwin L. Sessions, M.D. Louisville (Ky.) Medical College, 1879, died at his home in Hillsboro, Texas, October 12, from cerebral hemorrhage, after an illness of one week, aged 63.

John Slavens, M.D. University of Louisville (Ky.) Medical Department, 1848, an old resident of Putnam County, Indiana, died at his home in Brick Chapel October 10, aged 94.

John W. Ogilvie, M.D. Medical College of the State of South Carolina, Charleston, 1845, died at his home near Allendale, S. C., September 27, after a lingering illness, aged 87.

Percy E. Terry, M.D. Rush Medical College, Chicago; 1886 died at his home in Rochester, Ind., September 30, from spinal disease after an illness of two months, aged 44.

George W. Parsons, M.D. Cincinnati, 1864, a veteran of the Civil War, of Kansas City, Kan., died at the Soldiers' Home, Leavenworth, Kan., October 18, aged 68.

Thomas J. Peer, M.D. Illinois, 1872, of Ontario, N. Y., died suddenly in Rochester, N. Y., October 13, from heart disease, aged 63.

James E. Smith, M.D. Medical College of Ohio, Cincinnati, 1870, died at his home in Mauston, Wis., September 18, aged 57.

Samuel J. Wallace, M.D. Jefferson Medical College, Philadelphia, 1881, died at his home in Castine, Maine, September 28.

William Robinson, M.D. University of Buffalo (N. Y.) Medical Department, 1862, died at his home in Chicago, October 10

William H. Owsley, M.D. Examination Oklahoma, 1894, died at his home near Lexington, Okla., October 2, aged 60.

Ira D. Moser, M.D. Jefferson Medical College, 1880, of Philadelphia, died suddenly in Reading, Pa., October 21.

Book Notices

A Treatise on the Nervous Diseases of Children. For Physicians and Students. By B. Sachs, M.D. Second Edition. Cloth. Pp. 571. Price, $4.00. New York: Wm. Wood & Co.

The second edition of this work is 95 pages shorter than the edition of ten years ago, due to omission of the two chapters in the former edition on the anatomy and physiology of the spinal cord and the brain. The bibliographies and many detailed case reports are also omitted. A comparison of the texts of the chapters on hysteria, chorea and Pott's paralysis showed no significant changes. The chapter on insanity also is nearly the same as before, the former classification on mental disorders being retained in preference to that of Kraepelin.

A Text-Book of Medical Practice for Practitioners and Students. Edited by W. Bain, M.D. With Illustrations. Cloth. Pp. 1011. Price, $7.00 net. New York: Longmans, Green & Co. 1904.

The special feature of this text-book, which is a very commendable one, is the insertion of short articles on the anatomy, physiology and histology of the organ as a preface to the discussion of its diseased conditions. This is convenient and helpful to the practitioner and student who have finished with a study of their anatomy proper. These prefaces include a synopsis of the salient points on the anatomy, histology and physiology of the organ, such as the kidney, heart, liver. This feature is a new departure in a text-book of this sort and one that might be adapted to advantage in others.

The last chapter includes a discussion on the "interrelations" of organs in disease. These relations of certain organs to one another are shown in some cases to rest on an anatomic basis; in other instances they are dependent on a physiologic cause, such as the common relation between ovary and mammary gland. In still other cases, a pathologic relationship is presented, such as the effects of a diseased kidney on the heart. The book presents a good arrangement and classification of the different subjects. The list of contributors includes some of the best known English authors.

The Edinburgh Stereoscopic Atlas of Anatomy. Prepared under the auspices of the Department of Anatomy of the University of Edinburgh, by Professor J. R. Cunningham, M.D. (Edin. et Dubl.), D.S.c., LL.D. (Glasg. et St. And.), D.C.L. (Oxon.) Edited by David Waterston, M.A., M.D., F.R.C.S.E., F.R.S.E., Lecturer [illegible] in the Department of Anatomy, Edinburgh [illegible] ctions, 250 stereographs: Section 1—Central [illegible] ection 2—Thorax. Section 3—Abdomen and [illegible] Head and Neck. Section 5—Upper Limb: [illegible] section in a neat cloth case, titled on the back, suitable for placing in a bookcase. The complete set with stereoscope, $50. Sections 1 and 2 now ready. Imperial Publishing Co., No. 27 East 22d St., New York.

This consists of a stereoscope and 250 stereoscopic views of the various parts of the human body. The accuracy of the representations is guaranteed by the fact that they are photographs of representative specimens carefully dissected and labeled to show the various points of anatomy. Each view is on a card containing description. This series will be found of great value to any one who wishes to study anatomy and will be a valuable accessory to the manuals now in use in conjunction with work on the cadaver. The well-known clearness with which views of scenery are brought out by the stereoscope and the popularity of this instrument throughout the country makes it a little surprising that no adaptation of this principle to the study of the body has previously been made. The price of the set seems considerable, but the labor and expense required for its production is to be taken into consideration.

Text-Book of Physiological Chemistry for Students of Medicine. J. H. Long, M.S., Sc.D. Cloth. Pp. 424. Price, $2.50. Philadelphia: P. Blakiston's Son & Co., 1905.

In writing this new text-book Professor Long's aim has been "to present a brief account of the important principles of physiologic chemistry in a form suitable for the use of medical students who may be assumed to have completed courses in general inorganic and organic chemistry." The ground is fully covered in four sections devoted to the chemistry of the nutritives, of ferments and digestive processes, of the blood, the tissues and secretions of the body, and of the end products of metabolism, excretions, and the energy balance. Besides the descriptive matter, explicit instructions are given for an abundance of well-chosen laboratory experiments from which a selection can readily be made so that the book may serve as a laboratory manual as well as a text-book. Himself an investigator and a contributor of many new results to the science of physiologic chemistry, it is not surprising to find that Professor Long has not only brought his book up to date in the matter of new discoveries and modern theories and methods, but that he has also succeeded in producing in every part of the work the altogether satisfying impression that physiologic chemistry is not a cut and dried science but a rapidly growing one, in which knowledge is daily being increased by observation and experiment, theories modified, abandoned and created, and in which particularly large gaps are still frankly left for the genius of investigation to fill. This spirit is bound to have the excellent effect that the student will know that his study of physiologic chemistry must not stop with the curriculum of a medical school, but must continue through his later career; the fair, conservative weighing of evidence, the critical, relentless attitude of the real scientist shown in the book, will prepare the student admirably for selecting maturely his own conclusions from his later readings in medical and chemical journals. It will also probably inspire him to wish to contribute in some measure himself by observation or experiment to the growing science. For the same reasons the present practitioner will find this new text-book a lucid guide through most of the recent developments in physiologic chemistry. Special chapters are devoted to an outline of the chemical phases of some of the recent theories of immunity as well as to important applications of the methods of physical chemistry to medical work, notably of cryoscopy and electrical conductivity. A thorough exposition is given of the most recent work and ideas concerning those important agents, the enzymes, and the rôle played by the physicochemical behavior of salts as electrolytes and of colloids as subject to electrical changes is touched on. Good paper, large, clear type and a very full index are some of the best mechanical features of the book. Few typographical errors were observed, the only two of any moment noted being in the chemical equations on pages 123 and 316.

The Royal Medical and Chirurgical Society of London, Centenary 1805-1905. Written at the request of the President and Council by N. Moore, M.D., F.R.C.P., and S. Paget, F.R.C.S. Cloth. Pp. 337. Aberdeen University Press, Limited. 1905.

This is a history of what we believe is the oldest medical society in London, based on the recorded minutes of the society. Besides the usual matter, the minutes contained the titles and, in some instances, abstracts of the papers read, and the important ones are selected for mention. Among them will be found the most epoch-making papers of the past one hundred years. For during nearly all these years the Medico-Chirurgical Society of London has been one of the most important local societies in the world and has numbered among its members some of the well-known physicians and surgeons of England. Among those who were instrumental in its organization were: Abernethy, Atley, Cooper, Hunter, Edward Jenner, Bright, and others whose names are almost as familiar. It is interesting to read of the struggle, the self-sacrifice—both in time and money—that was required of the members on many occasions to keep the society up to the standard originally set for it. But it was kept up and, while the average attendance was seldom large, the work accomplished, as revealed by the minutes and especially by the transactions, was of the highest order and was probably excelled by no other medical society. There were some battles royal during the century, but none more virile than those in 1880-81 between Lawson Tait and his adherents on one side and Knowsley Thornton and Spencer Wells on the other on the then live question of Listerism. The following quotations from the minutes of the first meeting in 1881 make interesting reading after 25 years.

Mr. Thornton, at the first meeting of the year, presented to the society the tables of 172 antiseptic abdominal sections:

> "The cases have all been treated on one common plan, viz., by Lister's method. When I say this, I mean by Lister's own method, to the exclusion of all so-called modified Listerism. They have nearly all been also treated by 'complete intraperitoneal ligature.' There is, I am afraid, a growing tendency to ascribe to Lister's method bad results, which should more properly be ascribed to imperfect knowledge of Lister's teaching, and to consequent imperfect application of his method. As a result of this imperfect knowledge and performance, we have endless varieties of so-called modified Listerism, the modification generally striking so deeply at the foundations of true Listerism that it is an absurdity to attempt to connect such methods with his, even in name. The fact that, by rigid adherence to the teachings of my old master, I have in one of the operations (ovariotomy) steadily improved my results, lowering my rate of mortality from 23.94 per cent. to 4 per cent., is to me a sufficient reward for resisting this craze for variety."

Sir Spencer Wells, February 22, presented 200 additional cases of ovariotomy, making 1,000 cases in all, and said:

> "To my mind, one great merit of the antiseptic system is that it has made the intraperitoneal method, which was formerly the less, now the more successful method of dealing with the pedicle. Another great gain from the antiseptic system is that drainage of the peritoneal cavity is now scarcely ever necessary. My own experience has not only convinced me that by the use of antiseptics, especially of phenol, the success of ovariotomy has been remarkably increased, that a much smaller proportion of deaths to recoveries has been obtained; but, further, that those who have recovered have suffered much less from fever, while convalescence has been more rapid than it used to be."

The book will be found of interest to those who have a liking for medical history, to those who want to peer into the past, and to those who desire to come into direct contact, as it were, with the men who made English medicine.

PARALYSIS AND OTHER DISEASES OF THE NERVOUS SYSTEM, in Childhood and Early Life. By James Taylor, M.A., M.D., F.R.C.P. Cloth. Pp. 512. Price, $4.00 net. Philadelphia: P. Blakiston's Son & Co. 1905.

In his preface the author says that this book "is, in effect, an expression of personal opinions, the result of the writer's observations, modified and extended by his knowledge of the views of others, on subjects which have interested him for a good many years, and in regard to which he had the good fortune to have special opportunities of acquiring experience." It certainly is written from the standpoint of the writer. Apparently, he has treated the different diseases at a length proportioned to his interest in them, and the same is true of the different parts of the several subjects. Had he kept the reader and his needs more in mind the book might be much more valuable. The matter of treatment in detail seems to interest the author but little, even in such diseases as chorea and epilepsy, and consequently, throughout the work receives rather cursory and perfunctory attention. As further evidence of this personal bias may be mentioned the paltry three pages devoted to epidemic cerebrospinal meningitis, and nine pages on convulsions in childhood, while syringomyelia receives eighteen pages. There is a chapter on stammering in which the physiology of this disorder is treated, but in a way beyond criticism, but as to putting the reader in a position to treat a single case—the entire chapter might just as well have been omitted.

Some parts of the book are exceedingly good. The chapter on intracranial tumors is more than good; it is exceptionally fine. There are sixty-three pages of it; it is eminently practical and full of information. It will be helpful alike to student, general practitioner, pediatrist, surgeon and neurologist. The subjects of infantile hemiplegia and cerebral diplegia are very well done, anterior poliomyelitis (infantile paralysis) receives adequate attention, and the chapters on Friedreich's ataxia, muscular dystrophy and epilepsy are good. Many of the short chapters on less familiar diseases will be useful to student and practitioner. Among these may be mentioned posterior basic meningitis, amaurotic family idiocy, achondroplasia, hemicrania and third nerve paralysis (migraine ophthalmoplegique), hereditary optic atrophy and family periodic paralysis. Why the author should omit serous meningitis he alone knows. To write somewhat at length on juvenile general paralysis, cretinism and mongolian imbecility and say no word of dementia præcox, seems unusual. Three or four pages are given over to "functional paraplegia," which seems to have greatly mystified the author, but in the entire book there is nothing at all about hysterical paralysis. Nor has the reviewer been able to find anything on the paralysis of multiple neuritis in children, although the disease is far from rare. Laryngismus stridulus is surely a nervous disease of childhood, but it is quite overlooked.

In short, the book is useful, but of most unequal value. It will serve well as an adjunct to other books. In it the searcher is liable to find that for which he hunts and likely to find it not. It is too good to be ignored, not good enough to set great store by. The pediatrist and neurologist will want it, and the general practitioner who is a student can use it to advantage.

TEXT-BOOK OF PHYSIOLOGY, Normal and Pathological, for Students and Practitioners of Medicine. W. S. Hall, Ph.D. Second edition Revised and enlarged; 340 engravings and Three Colored Plates. Cloth. Pp. 795. Price, $4.00 net. Philadelphia: Lea Brothers & Co. 1905.

The principal, older, well-established facts of physiology, especially physical, are concisely and clearly stated in Professor Hall's book, but we are surprised to find that practically no mention is made of recent work concerning the rôle of physico-chemical factors in fundamental physiologic processes. Whatever the reason may be, this omission weakens the value of the book, because it fails to give the student any adequate indication of the direction in which physiology is growing at present. The newer knowledge of the normal protective powers of the blood against infection, of its solvent action on alien corpuscles, and other normal properties of this kind are not considered. Throughout the book great stress is placed on morphologic considerations. The chapter on reproduction, for example, is principally descriptive in its character; it might answer very well for a book on embryology, but the underlying causes of the various phenomena described, or the present theories of those causes, are not discussed. The chapters on digestion and metabolism give a clear statement of the many complex processes, chemical and physical, that here come into play. "The most notable additions to the work are the sub-chapters on 'Pathologic Physiology.' It is becoming apparent to medical educators that to master normal physiology alone without applying its laws to the symptomatology of disease is to miss a large part of the service which physiology should render, just as the mastery of structural or morphologic pathology without an understanding of the modification which structural changes induce in the functions, implies the loss of a large part of the advantage which the study of pathology should give to the student and practitioner of medicine. The author has attempted to cover this most important field." According to this extract from the preface, one would naturally look for carefully digested discussion of certain phases of true pathologic physiology, but instead we find inserted brief synopses mostly from the pens of instructors in different laboratories of the pathology (meaning pathologic anatomy), symptomatology and physiology of some of the principal diseases of the most important systems of organs. Some of these synopses are accompanied with rather loosely constructed bibliographic lists. The synopses are in reality condensed statements and tabulations of matter presented fully in books dealing with medicine and surgery, and their introduction here hardly warrants the title of the book, "A Text-Book of Normal and Pathological Physiology." In a book described by this title we expect to find discussions of general pathologico-physiologic problems, and we trust that in coming editions Professor Hall will take a broader and more general view of the important subject of pathologic physiology. By so doing we believe he will promote the services of physiology to practical medicine more successfully than by the present method, which in reality only touches on special points in pathologic physiology. Large bodies of facts are not handled and discussed in such a way that any general deductions can be drawn and general laws formulated. In spite of the shortcomings here outlined, many teachers of physiology will be grateful for having within easy reach so much of the physiologic knowledge considered essential to medical education.

Miscellany

To Disguise Taste of Quinin.—Yvon writes to the *Gaz. des Hôp.* to the effect that a mixture of fat prevents the saliva from dissolving quinin and thus disguises its taste in the mouth. He mixes from 15 to 20 per cent. olive or vaselin oil with the quinin after dissolving the oil in ether. The mixture is then flavored with peppermint or some other aromatic oil; the ether is allowed to evaporate, and the mixture is taken with water or some other fluid.

Clips in Appendix.—Potherat reported to the French Société de Chirurgie the finding of two Michel clips in the appendix in a case of perforating appendicitis. These little clips (*agrafes*), are being extensively used to hold wound edges together, to help in suturing or to take the place of a suture. In the present case they had been used in a preceding operation on this patient for the removal of an ovarian cyst. It was not explained how the clamps had reached the appendix.

Milk Diet in Scarlet Fever to Prevent Nephritis.—Ziegler states that he has not had a single case of nephritis during the last twenty-one years among 231 children with scarlet fever whom he kept on an exclusive milk diet. Before he made this the rule he encountered nephritis in fully half of all his cases of scarlet fever. During this period also he observed 9 cases of nephritis among 10 children who were not put on the milk diet. His communication was originally published in the *Cbl. f. Kinderheilkunde* last May.

Collodion When a Nail Is Being Thrown Off.—The painfulness of the loss of a nail can be prevented by applying collodion to the spot. It holds the old nail firmly in place and protects the new nail tissue that is forming, while it does not interfere with the growth of the latter. The *Corr.-bl. f. Schweiz. Aerzte* for October 1 cites Porosz to the above effect, adding his warning that the collodion must not be applied to the skin, but merely to the bed of the nail.

Circumcision of Mohammedan Children.—The Constantinople correspondent of the *Lancet* states that one of the curious acts of benevolence which the Sultan exercises on festive occasions is the circumcision of poor Mohammedan children at the expense of his private purse. Recently about 3,000 children were thus circumcised at the Hamidié Hospital. Every one of them received also, after the performance of the religious operation, presents from the Sultan. The operation was performed by twenty medical men in co-operation with the hodjas of the Islam. The usual age at which Mohammedan children are circumcised is 13 years, but this varies greatly according to circumstances. It very frequently happens that Mussulmans are subjected to the religious operation at the age of 20 years and even later.

Swallowing Lint After Sharp Foreign Bodies.—A Russian confrère, N. Otcheredin, writes to the *Vratchebnaya Gazeta*, for September 3, that he succeeded in promoting the passage and safe evacuation without apparent injury of two sharp tacks swallowed by a lad of 9. He fed the boy with a thick potato gruel made with milk into which he stirred a large quantity of fresh lint from a clean rag. The child was brought to him about fifteen minutes after the tacks had been swallowed, and about a glass and a quarter of this potato and lint puree were ingested. Six hours later he was given two tablespoonfuls of castor oil. The two tacks enveloped in lint were found in his stool the same evening. In this country slippery elm bark has been used with success. The lint is a valuable idea, especially for young children.

Exanthem a Natural Revulsion.—Einisse writes to the *Vratchebnaya Gazeta* of August 13 to suggest that the exanthem of the eruptive fevers, etc., may be merely a means of revulsion adopted by nature. The eruption should be promoted in every way to favor hyperemia of the skin. He has found the best measure for the purpose is to wrap the patient in a blanket after a warm bath. In two cases of erythema nodosum he noted that the intense painfulness of the joints subsided as the eruption of an intercurrent scarlet fever developed. The symptoms in another patient simulated those of appendicitis, but they all vanished as a measles eruption appeared. The benefit from an intercurrent eruptive affection in certain diseases is a familiar fact, and is probably the result of the exanthem which nature uses as a revulsive measure.

Queries and Minor Notes

PHYSICIANS' CARDS IN NEWSPAPERS.

Here is another amusing card to add to those already reproduced in these columns. We have substituted other names for the real ones.

DR. J. MARK DOE,
Physician and Surgeon.
Office at Four Corners. *Open Day and Night.*
Medicines, Fruit and Candy,
Notions and Sundries.
Soft Drinks, Canned Goods
and Lunch, etc.
Sherington, Daconsota.

This appeared in a weekly paper in a small inland hamlet in one of the northern states. The population of the place is perhaps not sufficient to support a physician, a druggist, a confectioner, a dry-goods merchant, a grocer and a restauranteur separately.

MEDICAL RECIPROCITY.

Dr. N. K., after reading the letter from Dr. Aronson, in The Journal, October 21, p. 1261, was reminded of a case in which reciprocity was strongly indicated, but was not forthcoming, and which, in his opinion, shows how unjust are the laws under which some medical examining boards have to operate. The candidate, aged 49, has been an honorable practitioner of medicine for the last twenty-seven years, is a graduate of two prominent medical schools, has been in continued practice since graduation, and, although his time was very much taken up "relieving suffering and prolonging life." he found enough time to keep up with the times by reading good medical journals and standard text-books, etc. In order to regain his lost health, due to long years of country practice, he decided to change climate, and went to a certain western state that requires an examination, or will reciprocate with certain other states, providing the candidate has a certificate "by examination" from one of these states. This candidate prepared for the examination for three months. During this time he practiced under a temporary certificate, but to his sorrow, after the examination, learned that he, like the fair flower, had been "plucked." This means three more months of hard work, and should he fail again, a move to another, perhaps *more merciful*, state. Of the recent graduate, who should, and easily can, pass examinations, this board requires none, providing the candidate once took an examination before a board reciprocating with this one. As examinations in nearly all states are recent requirements, it gives the old man, who *has devoted his* life to others, the "double cross." In other words, concludes our correspondent, the one of whom he writes was careless in the selection of his parents; he was born too soon.

DISPOSAL OF WASTE.

——— Ill., Oct. 20, 1905.

To the Editor:—Can you advise me of sources of information on the disposal of garbage and other refuse matter, incinerators, etc.?
S. C.

Answer.—The results of American experience are embodied in the reports and papers of the American Public Health Association during the last few years. The "Report of the Committee on Disposal of Garbage and Refuse" in 1897-98 and that in 1902 are especially valuable. In the "Proceedings of the Twenty-ninth Annual Meeting of the American Public Health Association (Buffalo, 1901), are two important papers on refuse disposal in the District of Columbia and in Boston. For publications of this body, if not accessible in libraries within reach, address the secretary, Dr. Charles O. Probst, Columbus, Ohio. Reference may also be made to a paper on "Incineration and Cremation of Waste," in *Municipal News* (Municipal News Assoc., 309 Broadway, New York), Sept. 25, 1905, in which statements are made concerning the present methods of garbage disposal in a number of American cities.

State Boards of Registration

COMING EXAMINATIONS.

Nebraska State Board of Health, State House, Lincoln, November 8-9. Secretary, George H. Brash, Beatrice.

Board of Registration in Medicine of Massachusetts, State House, Boston, November 14-15. Secretary, E. B. Harvey, Boston.

Connecticut Medical Examining Board, City Hall, New Haven, November 14-15. Secretary, Charles A. Tuttle, New Haven.

State Board of Health of Louisiana, New Orleans, November 14-15. Secretary, F. A. Larue, New Orleans.

State Board of Health of West Virginia, Clarksburg, November 14-16. Secretary, H. A. Barbee, Pt. Pleasant.

New Louisiana Examination Dates.—The fall examination of the Louisiana State Board of Medical Examiners did not take place on October 20 to 21, as had been announced, but was postponed because of quarantine regulations. November 14 and 15 are the new dates set.

Arkansas October Report.—Dr. J. P. Runyan, secretary of the State Medical Board of the Arkansas Medical Society, reports the written examination held at Little Rock, Oct. 10, 1905. The number of subjects examined in was 7; total number of questions asked, 60; percentage required to pass, 75. The total number of candidates examined was 14, of whom 7 passed, including an undergraduate, and 7 failed. Representatives of the following colleges passed:

PASSED.

College.	Year. Grad.	Per Cent.
University of Missouri	(1904)	81.8
Chattanooga Med. Coll.	(1905)	82.8
St. Louis University	(1905)	80
University of Arkansas (undergraduate)		80
Tulane University	(1873)	84
College of P. and S., Atlanta	(1905)	81.7
University of Tennessee	(1901)	75

A graduate of the University of Arkansas (1886) and one of the Memphis Hospital Medical College (1895) were granted license to practice under the old registration law.

Minnesota October Report.—Dr. C. J. Ringnell, secretary of the Minnesota State Board of Medical Examiners, reports the written examination held at St. Paul, Oct. 3-5, 1905. The number of subjects examined in was 12; total number of questions asked, 95; percentage required to pass, 75. The total number of candidates examined was 25, of whom 14 passed and 11 failed. Representatives of the following colleges passed:

PASSED.

College.	Year. Grad.	Per Cent.
University of Minnesota	(1905)	78.5
Northwestern University, (1903) 82.4; (1904) 81;	(1905)	75.1
McGill University	(1904)	79.2
College of P. and S., Chicago ......(1898) 75.4;	(1902)	76.2
Rush Med. Coll.......(1896) 80.1; (1903) 82.6;	(1905)	79.8
Western Med. Coll., Ontario	(1905)	86.4
Hahnemann Med. Coll., Chicago	(1904)	75.3
Hahnemann Med. Coll., Philadelphia	(1886)	75
George Washington Univ., Washington, D. C.	(1905)	79.4

Rhode Island October Report.—Dr. G. T. Swarts, secretary of the Rhode Island State Board of Health, reports the written examination held at Providence, Oct. 5-6, 1905. The number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 75. The total number of candidates examined was 19, of whom 12 passed and 7 failed. Representatives of the following colleges passed:

PASSED.

College.	Year. Grad.	Per Cent.
Baltimore Med. Coll.	(1905)	75
College of P. and S. Baltimore	(1905)	83.9, 84.2
College of P. and S. Boston	(——)	75
Harvard University	(1904)	87.1
Jefferson Med. Coll.	(1905)	79.5
Laval University	(1905)	75.4, 75.6
[illegible]ege, Philadelphia	(1905)	76.5
[illegible] Med. Coll.	(1894)	78.7
[illegible] ....(1898) 82.4;	(1903)	75

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending October 28.

Johnson, Richard W., surgeon, ordered, as additional duty to take charge of office of chief surgeon, Department of the Missouri, temporarily.

Munson, Edward L., asst.-surgeon, left Washington, D. C., on leave of absence for two months.

McAndrew, Patrick H., asst.-surgeon, granted leave of absence for one month.

Owen, William O., surgeon, ordered to San Francisco, Cal., for examination by army retiring board.

Carter, W. Fitzhugh, surgeon, ordered from San Francisco, Cal., to Fort Monroe, Va., for duty.

Rafferty, Ogden, surgeon, ordered from Fort Monroe, Va., to San Juan, P. R., for duty.

Lippitt, William F., surgeon, ordered from San Juan, P. R., to Fort Assinniboine, Mont., for duty.

Eastman, William R., asst.-surgon, ordered from San Francisco, Cal., to Army General Hospital, Presidio, San Francisco, Cal., for duty.

Noble, Robert E., asst.-surgeon, ordered from Army General Hospital, Presidio, San Francisco, Cal., to the Depot of Recruits and Casuals, *Angel Island, Cal., for duty.*

Lanister, William B., surgeon, returned to Jefferson Barracks, Mo., *from leave of absence.*

Glennan, James D., surgeon, returned to Fort Myer, Va., from leave of absence.

Quinton, William W., asst. surgeon, left Fort Barrancas, Fla., for his proper station, Fort McPherson, Ga.

Devereux, John R., asst.-surgeon, returned to Fort Logan, Colo., from leave of absence.

Boyer, Perry L., asst.-surgeon, leave of absence extended two months.

Woodbury, Frank T., a[illegible] New York, N. Y., for San Francisco, Cal., en [illegible] service.

Vose, William E., asst[illegible] Sheridan, Ill., for San Francisco, Cal., en route to Philippine service.

DeLoffre, Samuel M., asst. surgeon, relieved from duty at Fort Schuyler, N. Y., to proceed to San Francisco, Cal., for Philippine service.

Dale, Frederick A., asst.-surgeon, arrived at Fort Walla Walla, Washington, for duty.

Shortlidge, Edmund D., asst.-surgeon, left Wilmington, Del., for *San Francisco, Cal., en route to Philippine service.*

Edger, Benjamin J., Jr., asst.-surgeon, left Fort Brown, Texas, on leave of absence for four months.

Bourke, James, asst.-surgeon, relieved from temporary duty at Fort Howard, Md., and returned to Medical Supply Depot, New *York City, N. Y.*

Reagles, James, contract surgeon, leave of absence extended twenty days.

Sievers, Robert E., contract surgeon, granted leave of absence for three months.

Parkman, Wallace E., contract surgeon, granted leave of absence for *one month.*

Rebert, M. A., contract surgeon, ordered from Fort Totten, N. Y., to Fort Schuyler, N. Y., for temporary duty.

de Quevedo, Luis G., contract surgeon, returned to San Juan, P. R., from temporary duty at Henry Barracks.

McAlister, John A., dental surgeon, granted leave of absence for two months.

Newlove, George, contract surgeon, granted an extension of one month to his leave of absence.

Warwick, Clarence A., contract surgeon, relieved from duty in the Philippines Division, and ordered to duty at Fort Mott, N. J.

Sparrenberger, Frederick H., contract surgeon, relieved from duty at Fort Mott, N. J., and ordered to Fort Washakie, Wyo., for duty.

Kuhn, Charles F., contract surgeon, relieved from duty in the Philippines Division and ordered to Fort Lawton, Wash., for duty.

Purnell, Julius M., contract surgeon, relieved from duty in the Philippines Division, and ordered to duty in the Department of California.

Wythe, Stephen, contract surgeon, relieved from duty in the Department of California, and ordered to the Philippines Division for duty.

Stuckey, Harrison W., contract surgeon, arrived at Fort Snelling, Minn., for duty.

Cass, William E., contract surgeon, arrived at Fort Stevens, Oregon, for temporary duty.

Kellogg, Preston S., contract surgeon, ordered from San Francisco, Cal., to his home at Battle Creek, Mich., for annulment of contract.

Dade, Walter H., contract surgeon, left Fort Du Chesne, Utah, for duty at Fort D. A. Russell, Wyo.

Clayton, George R., contract surgeon, left Columbus Barracks, Ohio, for San Francisco, Cal., en route to Philippine service.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending October 28:

Stepp, J., P. A. surgeon, ordered to the *Southery*, and to additional duty at the navy yard, Portsmouth, N. H.

Dabney, V., acting asst.-surgeon, detached from the *Southery*, ordered home and resignation as acting assistant surgeon accepted, to take effect November 6.

Law, H. L., surgeon, retired, ordered to the naval recruiting rendezvous, Boston, November 3.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending October 25:

Vaughan, George T., assistant surgeon-general, granted leave of absence for three days from October 25.

Sawtelle, H. W., surgeon, granted leave of absence for one month from October 23.

Stoner, G. W., surgeon, granted leave of absence for 12 days from October 18, under the *provisions* of paragraph 189 of the regulations.

Wickes, H. W., P. A. surgeon, granted two days leave of absence from October 26.

Anderson, J. F., P. A. surgeon, granted leave of absence for one month from November 1.

Robertson, H. McG., asst.-surgeon, granted leave of absence for six days from October 23.

Hunt, Reid, chief, division of pharmacology, Hygienic Laboratory, granted leave of absence for six days from October 23.

Addis, W. E., acting asst.-surgeon, granted leave of abbsence for seven days.

Lyall, R., acting asst.-surgeon, granted leave of absence for four days.

Hall, R. F., acting asst.-surgeon, granted leave of absence for seven days.

Goodman, F. S., pharmacist, relieved from special temporary duty at New Orleans and Patterson, La., and directed to rejoin station at Norfolk, Va.

Watters, M. H., pharmacist, relieved from duty in Bureau at Washington, and directed to proceed to Chicago, reporting *to the* medical officer in command for duty and assignment to quarters.

Society Proceedings

COMING MEETINGS.

American Academy of Medicine, Chicago, November 7-8.

Southern Surgical and Gynecological Association, Louisville, Ky., Dec. 12-14.

American Dermatological Association, New York, Dec. 28-30.

Western Surgical and Gynecological Association, Kansas City, Mo., Dec. 27-28.

KENTUCKY STATE MEDICAL ASSOCIATION.

Fifty-fifth Annual Meeting, held at Louisville, Oct. 18-20, 1905.

The President, Dr. F. H. Clarke, Lexington, in the Chair.

Election of Officers.

The following officers were elected for the ensuing year: President, Dr. C. Z. Aud, Cecilia; vice-presidents, Drs. Murison Dunn, Richmond; R. M. Coleman, Paducah, and J. M. Salman, Ashland; secretary, Dr. James B. Bullitt, Louisville; treasurer, Dr. W. B. McClure, Lexington; orator in medicine, Dr. W. A. Jenkins, Louisville; orator in surgery, Dr. W. O. Bullock, Lexington; delegate to the American Medical Association, Dr. J. Garland Sherrill, Louisville.

Owensboro was selected as the next place of meeting.

Council on Pharmacy and Chemistry Approved.

On motion of Dr. A. T. McCormack, Bowling Green, the association pledged to the Council on Pharmacy and Chemistry of the American Medical Association its most earnest support in the work the council is doing.

On motion of Dr. C. M. Pope, the house of delegates was instructed to extend a vote of thanks to the various lay journals who are making a fight against the patent medicine evil, and tendering them the support of the association.

Dr. W. B. McClure, Lexington, introduced a resolution indorsing the name of Dr. Ephraim McDowell for a place in Statuary Hall in Washington.

Dr. J. M. Mathews, Louisville, introduced the following resolution, which was adopted:

> Whereas, The Honorable John W. Yerkes, commissioner of internal revenue for the United States Government, has recently promulgated and is now enforcing an order that all patent medicines containing over a certain per cent. of alcohol shall be held unsaleable unless the dealer takes out a retail liquor license,
>
> *Therefore*, Be it resolved that the Kentucky State Medical Association endorse and commend this action of the commissioner of internal revenue.

Relation of the Physician to the Community.

Dr. Clarke, in his president's address, spoke of organization in general and referred particularly to the importance of the organization movement carried on by the American Medical Association and the beneficial effect of that movement on the progress of medicine as a science. Among other topics discussed by Dr. Clarke were the relation of the physician to his community as a teacher of sanitation; hygiene and the prevention of disease; the regulation of medical registration; the suppression of the irregular practitioner; the sale of patent medicines; the management of charitable institutions; state provision for the care of epileptics and the treatment of inebriates, and the building of hospitals by the state for the treatment of consumptives.

Laboratory Methods.

Dr. J. F. McClymonds, Lexington, chose for his topic for the oration in medicine, "The Relation of Laboratory Methods to Medicine." He reviewed the history of the epoch-making discoveries in medicine, such as the demonstration of bacteria and their relation to disease; the discovery of the stethoscope; the development of chemistry and its relation to medicine; the development of pathology and bacteriology; the relation to disease of animal parasites; the serum diagnosis of disease, and the value of laboratory examination in the diagnosis of such diseases as anemia, chlorosis, tuberculosis, diphtheria, typhoid fever, malaria, etc., and the invention of the compound microscope. He said that to the initiated the laboratory is a blessing; to the uninitiated it is a curse.

Surgery of Gastric Ulcer.

Dr. Louis Frank, Louisville, in the oration on surgery, discussed the present status of gastric surgery with special reference to ulcer. He suggested early exploratory incision in doubtful cases where there is any suspicion of cancer, even when the laboratory diagnosis is negative. There is a time in the treatment of gastric ulcer when the surgeon must be called. Gastroenterostomy should be the operation of choice. The safest course is to secure all bleeding points and then to do the gastroenterostomy. He discussed the indications for surgical treatment, the treatment of gastrectasis and the ineffectiveness of medicinal measures. He scouted the value of test breakfasts and stomach washings in the diagnosis of gastric cancer.

Postpartum Infections.

Dr. Edward Speidel, Louisville, advocated the wearing of sterilized rubber gloves during the delivery of the patient, the administration of quinin to combat malarial infection, the stimulation of the hepatic function by means of intestinal flushing, and the use of vaginal douches after delivery. He said that neither the sharp nor the dull curette should be used in the parturient uterus. If curettage is indicated the finger is best for the purpose. If infection occurs and it extends beyond the uterus, its spread should be limited by following out the Ochsner treatment for appendicitis. Speidel also uses nuclein solution hypodermically, giving one ounce daily, and twice daily per rectum, seven and one-half grains of chloral dissolved in two ounces of water. Hysterectomy, he said, is indicated only when the infection is confined to the uterus.

Unique Case of Extrauterine Pregnancy.

Dr. J. R. Morrison, Louisville, reported a case in which rupture evidently occurred at about the fourth month, the fetus becoming encysted. The patient had severe pains for about five months afterward. A diagnosis was made of fibroid of the uterus and a laparotomy was performed. However, the tumor was found to be so adherent, and the patient's condition was so poor that the operation was not concluded. The laparotomy wound did not heal up entirely, and two years later there were discharged through the wound the bones of a fetal skeleton of about four months' development.

College Education Preparatory to Medicine.

Dr. J. W. Pryor, Lexington, described the course leading to the degree of B.S. given by the State College of Kentucky, the last two years of this course being really preparatory to the study of medicine, and advocated such a preparation for all prospective students of medicine.

The Irregular Regular.

Dr. G. E. Davis, Lawrenceburg, spoke of graft of all kinds, especially medical graft, the profession of getting hurt, the division of fees, and the various subterfuges resorted to by some medical men to acquire a practice. He suggested that the organized profession bring such influence to bear on the public press that it will fight quackery and expose the methods of quacks.

Causes of Gastric Ulcer.

Dr. Charles G. Lucas, Louisville, advised that careful attention be paid to all cases where an injury to the epigastrium was sustained or where anemia develops. A blood examination should also be made as well as an estimation of the HCl content of the gastric juice.

Diagnosis and Treatment of Gastric Ulcer.

Dr. S. E. Woody, Louisville, discussed the differential diagnosis of cancer, ulcer, gastritis, vomiting of pregnancy, etc. He divided the treatment into five stages: 1, The treatment of urgent symptoms; 2, functional rest of stomach; 3, bland diet; 4, proper medicinal treatment to produce healing of the ulcer, and 5, these failing, surgery.

Capillary Bronchitis in Infants.

Dr. R. B. Gilbert, Louisville, called attention to the fact that in this condition it is important to treat the accompanying intestinal fermentation. He uses saline injections consisting of one heaping teaspoonful of ordinary salt in a pint of water, no medicine being given by mouth, so as to give the stomach complete functional rest. Locally he applies to the chest an ointment consisting of twenty grains of menthol to the ounce of vaselin.

The Tuberculosis Problem in the South.

Dr. Dunning S. Wilson, Louisville, cited statistics showing that in Kentucky, West Virginia and Tennessee the death rate from pulmonary tuberculosis is over 13 per cent. In Virginia, North Carolina and South Carolina it is over 11 per cent., while in Georgia, Alabama, Mississippi and Louisiana it is over 9 per cent. In Arkansas and Texas the death rate is over 7 per cent., and in Florida it is less than 7 per cent. The average death rate for all these states is 11.2 per cent. In the states having the largest negro population the mortality from tuberculosis is less than in states in which fewer negroes live. In states having cities of large size the mortality is greater than in those states where the population is confined to smaller towns. In Kentucky over 16 per cent live in towns of 8,000 and over. The percentage of deaths from tuberculosis among this number is 14.56 per cent., only 13 per cent. of the population being colored. In Louisiana 47.2 per cent. of the population is colored. Twenty-two per cent. of the entire population lives in cities of over 8,000, with a death rate of only 9.62 per cent. for the state. Among the twelve largest cities New Orleans ranks highest in the death rate from tuberculosis. Wilson says that the negro is susceptible not because of an inherited tendency, but because of his mode of living. An analysis of the figures cited shows that the negroes do not influence unfavorably the death rate from tuberculosis, as is generally supposed; the states having the largest negro population have the lowest mortality. He believes that tuberculosis is curable in any climate, providing proper attention is paid to rest, food and the breathing of fresh air. These patients should be given every care so that they will not be a menace to society, but they should not be considered as pariahs.

The following papers were also read: "Prevention and Treatment of Postpartum Infections," by Dr. Basil M. Taylor, Greensburg; "Rupture of the Uterus," by N. M. Garrett, Frankfort; "The Care of Breast and Nipple During Pregnancy and Puerperium," by Dr. R. N. Coleman, Lexington; "Pleurisy," by J. B. Jackson, Danville; "Infection and Contagion," by W. A. Jenkins, Louisville; "Practical Significance of Arterial Tension," by Dr. J. A. Flexner, Louisville;; "Acute Infantile Summer Diarrhea," by Dr. S. J. Harris, Philpot; "Gas Bacillus Infection," by Dr. R. L. Ireland, Louisville; "Nature and Causes of Rheumatism," by Dr. John G. Cecil, Louisville; "Complications of Rheumatism," by Dr. H. E. McKay, Bardstown; "Dionin in Diseases of the Eye," by Dr. S. G. Dabney, Louisville.

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES.

Fourteenth Annual Meeting, held in Detroit, Sept. 26-28, 1905.

(Continued from Page 1355.)

Unification of the Duties of Medical Officers.

Surgeon Charles S. Stokes, U. S. Navy, made a plea for the unification of the duties of medical officers of the army and navy, including the national guard and the naval militia. He said that the basis of existence was the same in all branches of the service and that the preliminary requirements were identical. He suggested service school instruction along the same lines, modified only to meet the variations dependent on service afloat or service ashore. He considered that the aims, personnel and material, as far as possible, should be the same. He urged the encouragement of healthful rivalry between the various branches of the service and especially the cultivation of an *esprit de corps*. He considered one of the chief values of the association the bringing together of surgeons of all branches of the service to discuss on an equal footing matters of interest to all. The training and drilling of enlisted men in the working details of military hygiene and first-aid methods he considered the most important problem to be solved by military surgeons and advocated the education of line officers in this regard. To establish a basis for work which would be applicable to all branches of the service, he advised the establishment of a joint board which should formulate the details of the plan of instruction in hygiene, first-aid, etc.

New Suture Materials.

Col. N. Senn, surgeon-general of Illinois, informally called attention to surgeons' new suture materials which he had obtained on his recent trip to Greenland. He presented suture material made from the tendon of the whale, the walrus and the narwhal, and also presented a vegetable fiber from New Zealand, the use of which he advised for superficial sutures.

In Manchuria with the Russians.

Col. Valery Havard, assistant surgeon-general, U. S. Army, who was detailed for duty with the Russian army in Manchuria, presented a detailed report of his experiences, in which he gave the ratio of killed to wounded in the Japanese army as 1 to 4.5 and in the Russian army as 1 to 3.96. The wounds from shrapnel comprised the greater majority as compared with those caused by bullets. He also stated that the wounds from bayonet and sword, weapons which have been generally considered obsolete, were still met with, and that before the battle of Mukden 500 Russians had been killed and wounded by the bayonet. The ratio of sick in the Russian army up to June 13, 1904, was 3.28 per cent. After the rainy season had set in, the ratio increased to 3.74 per cent., and on that date the number of cases of communicable disease was 1,117, including all cases of dysentery and diarrhea. At that time there were only 34 cases of typhoid fever, 15 of typhus fever and 9 of recurrent fever. On Dec. 8, 1904, there were in hospitals 819 officers and 17,384 soldiers. Two months later the number had increased to 873 officers and 17,892 soldiers.

The Russian statistics showed that during 1904 at least 20,000 Russians were killed in action or died from wounds, and that during the same period the number of deaths from disease was only 2,730, a ratio of about 7 to 1. He stated that in Manchuria epidemic diseases might have been expected to break out, but that, to his surprise, not only were such epidemics absent, but the usual camp diseases were not prevalent. The variation of percentage of infected wounds in summer and winter dependent on the condition of the skin and the amount of clothing worn by the soldiers was interesting. In Mukden hospitals hardly 10 per cent. of the wounds inflicted in summer were infected, while in winter hardly 10 per cent. of the wounds escaped infection, notwithstanding the primary dressings which had been applied in most cases. He concluded that the prophylactic measures preparatory to battle from a hygienic standpoint should be the taking of a bath, the donning of clean linen and a clean and light uniform, and that, although the soldier should be well fed, his intestines should be empty on the day of battle.

Effects of Big Gun Firing.

Fleet Surgeon Lloyd Thomas, R. N., of the Naval Gunnery School, Portsmouth, England, described the effects incident to the firing of the naval guns of the present day at sea. In barbettes and turrets the occupants suffered at first a feeling of shock and, in addition, a tendency to nausea. The injuries to the ears resultant on big guns firing were rupture of the membrana tympani, or what he termed "gun deafness," the latter being a permanent deafness due to injury from repeated shocks on the internal ear. The pathology of this condition was not clear. Up to the present nothing had been found which would efficiently protect the ear from the concussions due to the firing of heavy guns. Cotton wool, or other substances, had been devised and used for plugging the external meatus. It had been shown experimentally that the intensity of sound was weakened by filling the irregularities of the auricle with wax, oil or vaselin, but neither officers nor crew took kindly to such artificial means.

The Canteen.

Col. Jefferson D. Griffith, Kansas City, surgeon-general of Missouri, presented the following resolution, which was adopted:

Whereas, The abolition of the army canteen in the opinion of those best acquainted with the army, has resulted in the use of an increased amount of bad liquors, instead of light wines and beer as sold at the canteen by the soldiers, resulting in a marked increase in diseases tending to the demoralization of the soldier; and,

Whereas, It is found that the anti-canteen law adds to the number of saloons and brothels contiguous to garrisons, and as the result, the monthly stipends are spent outside altogether; and,

Whereas, No benefit whatsoever in any line has been the result of the abolition of the canteen; be it

Resolved, That this body in session do earnestly request the Secretary of War to use his every effort for the re-establishment of the canteen, assuring him of our hearty support in every manner.

Examination of Recruits.

Major Charles Adams, Chicago, surgeon Illinois National

Guard, made a report of the result of examination of recruits for National Guard service, with especial reference to the period since the Spanish-American war, in which he detailed the findings of examining officers for the last seven years, the proportion of physical disabilities found and their nature. He stated the endeavor should be to conform as closely as practicable to the rules and forms for the examination of recruits in use in the regular establishment.

Presentation of Insignia.

On the second day the insignia of the association was formally presented to the delegates from abroad, the presentation remarks being made by the secretary.

SECOND INTERNATIONAL SANITARY CONVENTION.

Held at Washington, D. C., Oct. 9-14, 1905.

(Concluded from page 1348.)

Sanitary Agreement.

October 13 and 14 were entirely devoted to the consideration and adoption of the following agreement:

The Presidents of the Republics of Chile, Costa Rica, Cuba, Dominican Republic, Ecuador, Guatemala, Mexico, Nicaragua, Peru, United States of America, and Venezuela: Having found that it is useful and convenient to codify all the measures destined to guard the public health against the invasion and propagation of yellow fever, plague and cholera, have designated as their delegates:

[Here follow the names of the delegates.]

Who, having made an interchange of their powers, and found them good, have agreed to adopt, *ad referendum*, the following propositions:

CHAPTER I.

REGULATIONS TO BE OBSERVED BY THE POWERS SIGNATORY TO THE CONVENTION AS SOON AS PLAGUE, CHOLERA, OR YELLOW FEVER MAY APPEAR IN THEIR TERRITORY.

Section I.—Notification and subsequent communications to other countries.

Article 1. Each government should immediately notify other governments of the first appearance in its territory of authentic cases of plague, cholera or yellow fever.

Article 2. This notification is to be accompanied, or very promptly followed, by the following additional information:

(1) The neighborhood where the disease has appeared.
(2) The date of its appearance, its origin, and its form.
(3) The number of established cases, and the number of deaths.
(4) For plague: The existence among rats or mice of plague, or of an unusual mortality. For yellow fever: The existence of *Stegomyia fasciata* in the locality.
(5) The measures taken immediately after the first appearance.

Article 3. The notification and the information prescribed in Articles 1 and 2 are to be addressed to diplomatic and consular agents in the capital of the infected country; but this is to be construed as not preventing direct communication between officials charged with the public health of the several countries.

For countries which are not thus represented, they are to be transmitted directly by telegraph to the governments of such countries.

Article 4. The *notification and the information prescribed* in Articles 1 and 2 are to be followed by further communications dispatched in a regular manner in order to keep the governments informed of the progress of the epidemic.

These communications, which are to be made at least once a week, and which are to be as complete as possible, should indicate in detail the precautions taken to prevent the extension of the disease.

They should set forth: First, the prophylactic measures taken relative to sanitary or medical inspection, to isolation and disinfection; Second, the measures taken relative to departing vessels to prevent the exportation of the disease, and, especially under the circumstances mentioned in paragraph 4 of Article 2 of this section, the measures taken against rats and mosquitoes.

Article 5. The prompt and faithful execution of the preceding provisions is of the very first importance.

The notifications only have a real value if each government is warned in time of cases of plague, cholera or yellow fever and of suspicious cases of those diseases supervening in its territory. It can not then be too strongly recommended to the various governments to make obligatory the declaration .of cases of plague, *cholera or yellow fever, and of giving information of all unusual* mortality of rats and mice especially in ports.

Article 6. It is understood that neighboring countries reserve to themselves the right to make special arrangements with a view of organizing a service of direct information between the chiefs of administration on the frontiers.

Section II. Conditions showing a given territorial area to be infected, or to have been freed from infection.

Article 7. Information of a first case of plague, cholera or yellow fever does not justify against a territorial area where it may appear, the application of the measures prescribed in Chapter 2 as hereinafter indicated.

On the occurrence of several non-imported cases of plague, or a non-imported case of yellow fever or when cases of cholera form a focus, the area is to be declared infected.

Article 8. To limit the measures to the affected regions alone, governments should only apply them to persons and articles proceeding from th [illegible] infected areas.

By the word [illegible] a well determined portion of territory describe[illegible] which accompanies or follows notification, thus, a province, a state, “a government,” a district, a department, a canton, an island, a commune, a city, a quarter of a city, a village, a port, a “polder,” a hamlet, etc., whatever may be the extent *and population of these portions of territory.*

But this restriction, limited to the infected area, should only be accepted on the formal condition that the government of the infected *country shall take the* necessary measures: 1, to prevent, unless *previously disinfected, the exportation of articles named* in 1 and 2 of Article 12, coming from the contaminated area; and 2, measures to prevent the extension of the epidemic; and provided further that there be no doubt that the sanitary authorities of the infected country have *faithfully complied with Article 1* of this convention.

When an area is infected, no restrictive measure is to be taken against departures from this area if these departures have occurred five days, at least, before the beginning of the epidemic.

Article 9. That an area should no longer be considered as infected, official proof must be furnished:

First, That there has been neither a death nor a new case of plague or cholera for five days after isolation,[1] death, or cure of the last plague or cholera case. In the case of yellow fever the period shall be eighteen days, but each government may reserve the right to extend this period.

Second, That all the measures of disinfection have been applied: in the case of plague, that the precautions against rats have been observed, and in the case of yellow fever that the measures against mosquitoes have been executed.

CHAPTER II.

MEASURES OF DEFENSE BY OTHER COUNTRIES AGAINST TERRITORIES DECLARED TO BE INFECTED.

Section I. Publication of prescribed measures.

Article 10. The government of each country is obliged to immediately publish the measures which it believes necessary to take against departures either from a country or from infected territorial area.

The said government is to communicate at once this publication to the diplomatic or consular agent of the infected country residing in its capital as well as to the International Sanitary Bureau.

The government shall be equally obliged to make known through the same channels the revocation of these measures or modifications which may be made in them.

In default of a diplomatic or consular agency in the capital, communications are made directly to the government of the country interested.

Section II. Merchandise—Disinfection—Importation and Transit—Baggage.

Article 11. There exists no merchandise which is of itself capable of transmitting plague, cholera or yellow fever. It only becomes dangerous in case it is soiled by pestous or choleraic products, or, in the case of yellow fever, when such merchandise may harbor mosquitoes.

Article 12. No merchandise or objects shall be subjected to disinfection on account of yellow fever, but in cases covered by the previous article the vehicle of transportation may be subjected to fumigation to destroy mosquitoes. In the case of cholera and plague disinfection should only be applied to merchandise and objects which the local sanitary authority considers as infected.

Nevertheless, merchandise, or objects enumerated hereafter, may be subjected to disinfection, or prohibited entry, independently of all proof that they may or may not be infected:

1. Body linen, wearing apparel in use, clothing which has been worn, bedding already used.

When these *objects are transported as baggage, or in the course* of a change of residence (household furniture), they should not be prohibited, and are to be subjected to the regulations prescribed by Article 19.

Baggage left by soldiers and sailors, and returned to their country after death, are considered as objects comprised in the first paragraph of No. 1 of this article.

2. Rags, and rags for making paper, with the exception, as to cholera, of rags [illegible] merchandise in large quantities compressed [illegible] by hoops.

New clippings [illegible] pinning mills, weaving mills, manufactories or bleacheries, shoddy, and clippings of new paper should not be fordidden.

Article 13. In the case of cholera and plague there is no reason to forbid the transit through an infected district of merchandise, and the objects specified in Nos. 1 and 2 of the preceding Article, if they are so packed that they can not have been exposed to infection in transit.

[illegible] when merchandise or objects are so transported [illegible] can not come in contact with soiled objects, [illegible] an infected territorial area should not be an [illegible] *y into the country* of destination.

Article 14. [illegible] ry of merchandise and objects specified in Nos. 1 and 2 of Article 12 should not be prohibited, if it can be shown to the authorities of the country of destination that they were *shipped at least five days* before the beginning of the epidemic.

Article 15. The method and place of disinfection, as well as the measures to be employed for the destruction of rats, and mosquitoes, on arrival *at said* destination, are to be fixed by authority of the country destination. These operations should be performed in such a manner as to cause the least possible *injury to the merchandise.*

It devolves on each country to determine questions relative to the payment of damages resulting from disinfection, *or* from the destruction of rats or mosquitoes.

If taxes are levied by a *sanitary authority*, either directly or through the agency of any company or agent, to insure measures for the destruction of rats and mosquitoes on board ships, the amount of these taxes ought to be fixed by a tariff published in advance, and the result of these measures should not be a source of profit for either state or sanitary authorities.

Article 16. Letters and correspondence, printed matter, books, newspapers, business papers, etc. (postal parcels not included), are not to be submitted to any restriction or disinfection. In case of yellow fever postal parcels are not to be subjected to any restrictions or disinfection.

---

[1] The word “isolation” signifies isolation of the patient, of the persons who care for him and the *forbiding* of visits of all other persons, the physician excepted. By isolation in the case of yellow fever is understood the isolation of the patient in an apartment so screened as to prevent the access of mosquitoes.

Article 17. Merchandise, arriving by land or by sea, should not be detained permanently at frontiers or in ports.

Measures which it is permissible to prescribe with respect to them are specified in Article 12.

Nevertheless, when merchandise, arriving by sea in bulk (vrac) or in defective packages, is contaminated by pest-stricken rats during the passage, and is incapable of being disinfected, the destruction of the germs may be assured by putting said merchandise in a warehouse for a period to be decided by the sanitary authorities of the port of arrival.

It is to be understood that the application of this last measure should not entail delay on any vessel nor extraordinary expenses resulting from the want of warehouses in ports.

Article 18. When merchandise has been disinfected by the application of the measures prescribed in Article 12, or put temporarily in warehouses in accordance with the third paragraph of Article 17, the owner, or his representative, has the right to demand from the sanitary authority which has ordered such disinfection, or storage, a certificate setting forth the measures taken.

Article 19. Baggage. In the case of soiled linen, bed clothing, clothing and objects forming a part of baggage or furniture coming from a territorial area declared contaminated, disinfection is only to be practiced in cases where the sanitary authority considers them as contaminated. There shall be no disinfection of baggage on account of yellow fever.

Section III. Measures in ports and at maritime frontiers.

Article 20. Classification of ships. A ship is considered as infected which has plague, cholera or yellow fever on board, or which has presented one or more cases of plague or cholera within seven days, or a case of yellow fever at any time during the voyage.

A ship is considered as suspected on board of which there have been a case or cases of plague or cholera at the time of departure or during the voyage, but no new case within seven days; also such ships as have lain in such proximity to the infected shore as to render them liable to the access of mosquitoes.

The ship is considered *indemne*, which, although coming from an infected port, has had neither death nor case of plague, cholera or yellow fever on board, either before departure, during the voyage, or at the time of arrival, and which in the case of yellow fever has not lain in such proximity to the shore, as to render it liable, in the opinion of the sanitary authorities, to the access of mosquitoes.

Article 21. Ships infected with plague are to be subjected to the following regulations:

1. Medical visit (inspection).
2. The sick are to be immediately disembarked and isolated.
3. Other persons should also be disembarked, if possible, and subjected to an observation,[2] which should not exceed five days dating from the day of arrival.
4. Soiled linen, personal effects in use, the belongings of crew[3] and passengers which, in the opinion of the sanitary authorities are considered as infected should be disinfected.
5. The parts of the ship which have been inhabited by those stricken with plague, and such others as, in the opinion of the sanitary authorities are considered as infected, should be disinfected.
6. The destruction of rats on shipboard should be effected before or after the discharge of cargo, as rapidly as possible, and in all cases with a maximum delay of forty-eight hours, care being taken to avoid damage of merchandise, the vessel and its machinery.

   For ships in ballast, this operation should be performed immediately before taking on cargo.

Article 22. Ships suspected of plague, are to be subjected to the measures which are indicated in Nos. 1, 4 and 5 of Article 21.

Further, the crew and passengers may be subjected to observation, which should not exceed five days, dating from the arrival of the ship. During the same time, the disembarkment of the crew may be forbidden, except for reasons of duty.

The destruction of rats on shipboard is recommended. This destruction is to be effected before or after the discharge of cargo, as quickly as possible, and in all cases with a maximum delay of forty-eight hours, taking care to avoid damage to merchandise, ships, and their machinery.

For ships in ballast, this operation should be done, if done at all, as early as possible, and in all cases before taking on cargo.

Article 23. Ships *indemne* from plague are to be admitted to free pratique immediately, whatever may be the nature of their bill of health.

The only regulation which the sanitary authorities at a port of arrival may prescribe for them consists of the following measures:

1. Medical visit (inspection).
2. Disinfection of soiled linen, articles of wearing apparel, and the other personal effects of the crew and passengers, but only in exceptional cases when the sanitary authorities have special reason to believe them infected.
3. Without demanding it as a general rule, the sanitary authorities may subject ships coming from an infected port to a process for the destruction of the rats on board before or after the discharge of cargo. This operation should be done as soon as possible, and in all cases should not last more than twenty-four hours, care being taken to avoid damaging merchandise, ships, and their machinery, and without interfering with the passing of passengers and crew between the ship and the shore. For ships in ballast, this procedure, if practiced, should be put in operation as soon as possible, and in all cases before taking on cargo.

   When a ship coming from an infected port has been subjected to a process for the destruction of rats, this process should only be repeated if the ship has touched meanwhile at an infected port, and has been alongside a quay in such port, or if the presence of sick or dead rats on board is proved.

   The crew and passengers may be subjected to a surveillance, which should not exceed five days, to be computed from the date when the ship sailed from the infected port. The landing of the crew may also, during the same time, be forbidden except for reasons of duty.

   Competent authority at the port of arrival may always demand, under oath, a certificate of the ship's physician, or in default of a physician, of the captain, setting forth that there has not been a case of plague on board since departure, and that no marked mortality among the rats has been observed.

Article 24. When on an *indemne* ship rats have been recognized as pest-stricken as a result of bacteriologic examination, or when a marked mortality has been established among these rodents, the following measures should be applied:

1. *Ships with plague-stricken rats:*

(*a*) Medical visit (inspection).

(*b*) Rats should be destroyed before or after the discharge of cargo, as rapidly as possible, and in all cases with a delay not to exceed forty eight hours; the deterioration of merchandise, vessels and machinery to be avoided. On ships in ballast, this operation should be performed as soon as possible, and in all cases before taking on cargo.

(*c*) Such parts of the ship and such articles as the local sanitary authority regards as infected, shall be disinfected.

(*d*) Passengers and crew may be submitted to observation, the duration of which should not exceed five days, dating from the day of arrival, except in special cases where the sanitary authority may prolong the observation to a maximum of ten days.

2. *Ships where a marked mortality among rats is observed:*

(*a*) Medical visit (inspection).

(*b*) An examination of rats, with a view to determining the existence of plague, should be made as quickly as possible.

(*c*) If the destruction of rats is judged necessary, it shall be accomplished under the conditions indicated above in the case of ships with plague-stricken rats.

(*d*) Until all suspicion may be eliminated, the passengers and crew may be submitted to observation, the duration of which should not exceed five days counting from the date of arrival, except in special cases, when the sanitary authority may prolong the observation to a maximum of ten days.

Article 25. The sanitary authorities of the port must deliver to the captain, the owner, or his agent, whenever a demand for it is made, a certificate setting forth that the measures for the destruction of rats have been efficacious and indicating the reasons why these measures have been applied.

Article 26.—Ships infected with cholera are to be subjected to the following regulations:

1. Medical visit (inspection).
2. The sick are to be immediately disembarked and isolated.
3. Other persons ought also to be disembarked, if possible, and subjected, dating from the arrival of the ship, to an observation, the duration of which shall not exceed five days.
4. Soiled linen, wearing apparel, and personal effects of crew and passengers which, in the opinion of the sanitary authority of the port, are considered as infected, are to be disinfected.
5. The parts of the ship which have been inhabited by persons sick with cholera, or which are considered by the sanitary authority as infected are to be disinfected.
6. The bilge-water is to be discharged after disinfection.

   The sanitary authority may order the substitution of good potable water for that which is contained in the tanks on board.

   The discharge or throwing overboard into the water of a port, of dejecta, shall be forbidden unless they have been previously disinfected.

Article 27. Ships suspected of cholera are to be subjected to measures prescribed under Nos. 1, 4, 5 and 6 of Article 26.

The crew and passengers may be subjected to an observation which should not exceed five days, to date from the arrival of the ship. It [illegible] the same time to prevent the debarkation [illegible] reasons of duty.

Article [illegible] cholera are to be admitted to free pratique [illegible] may be the nature of their bill of health.

The only regulations which the sanitary authorities of a port may prescribe in their case are the measures provided in Nos. 1, 4 and 6 of Article 26.

The crews and passengers may be submitted, in order to show their state of health, to an observation, which should not exceed five days to be computed from the date when the ship sailed from the infected port.

It is recommended that during the same time the debarkation of the crew be forbidden except for reasons of duty.

Competent authority at the port of arrival may always demand, under oath, a certificate from the ship's surgeon, or, in the absence of a surgeon, from the captain, setting forth that there has not been a case of cholera on the ship since sailing.

Article 29. Competent authority will take account, in order to apply the measures indicated in Articles 21 to 28, of the presence of a physician on board and a disinfecting apparatus in ships of the three categories mentioned above.

In regard to plague, it will equally take account of the installation on board of apparatus for the destruction of rats.

Sanitary authorities of such countries, where it may be convenient to make such regulations, may dispense with the medical visit and other measures toward *indemne* ships which have on board a physician specially commissioned by their country.

Article 30. Special measures may be prescribed in regard to crowded ships, notably emigrant ships, or any other ship presenting bad hygienic conditions.

Article 31. Any ship not desiring to be subjected to the obligations imposed by the authority of the port in virtue of the stipulations of the present convention is free to proceed to sea.

It may be authorized to disembark its cargo after the necessary precautions shall have been taken; namely, First, isolation of the ship, its crew and passengers; second, in regard to plague, demand for information relative to the existence of an unusual mortality among rats; third, in regard to cholera, the discharge of the bilge-water after disinfection and the substitution of a good potable water for that which is provided on board the ship.

Authority may also be granted to disembark such passengers as may demand it, on condition that these submit themselves to all measures prescribed by the local authorities.

---

[2] The word "observation" signifies isolation of the passengers, either on board ship or at a sanitary station before being given free pratique.

[3] The term "crew" is applied to persons who may make, or, who have made, a part of the personnel of the vessel and of the administration thereof, including stewards, waiters, "cafedji," etc. The word is to be construed in this sense wherever employed in the present convention.

Article 32. Ships coming from a contaminated port, which have been disinfected and which may have been subjected to sanitary measures applied in an efficient manner, shall not undergo a second time the same measures on their arrival at a new port, provided that no new case shall have appeared since the disinfection was practiced, and that the ships have not touched in the meantime at an *infected port.*

When a ship only disembarks passengers and their baggage, or the mails, without having been in communication with *terra firma,* it is not to be considered as having touched at a port, provided that in the case of yellow fever it has not approached sufficiently near the shore to permit the access of mosquitoes.

Article 33. Passengers arriving on an infected ship have the right to demand of the sanitary authority of the port a certificate showing the date of their arrival and the measures to which they and their baggage have been *subjected.*

Article 34. Packet boats shall be subjected to special regulation, to be established by mutual agreement between the countries in interest.

Article 35. Without prejudice to the right which governments possess to agree on the organization of common sanitary stations, each country should provide at least one port on each of its seaboards, with an organization and equipment sufficient to receive a vessel, whatever may be its sanitary condition.

When an *indemne* vessel, coming from an infected port, arrives in a large mercantile port, it is recommended that she be not sent to another port for the execution of the prescribed sanitary measures.

In every country, ports liable to the arrival of vessels from ports infected with plague, cholera or yellow fever, should be equipped in such a manner that *indemne* vessels may there undergo, immediately on their arrival, the prescribed measures, and not be sent for this purpose to another port.

Governments should make declaration of the ports which are open in their territories to arrivals from ports infected with plague. *cholera or yellow fever.*

Article 36. It is recommended that in large seaports there be established:

(*a*) A regular medical service and a permanent medical supervision of the sanitary conditions of crews, and the inhabitants of the port.

(*b*) Places set apart for the isolation of the sick and the observation of suspected persons. In the stegomyia belt there must be a building or part of a building screened against mosquitoes, and a launch and ambulance similarly screened.

(*c*) The necessary installation for efficient disinfection and bacteriologic laboratories.

(*d*) A supply of potable water above suspicion, for the use of the port, and the installation of a system of sewerage and drainage, adequate for the removal of refuse.

Section IV. Measures on land frontiers. Travelers. Railroads. Frontier Zones. River Routes.

Article 37. Land quarantines should no longer be established, but the governments reserve the right to establish camps of observation if they should be thought necessary for the temporary detention of suspects.

This principle does not exclude the right for each country to close a part of its frontier in case of necessity.

Article 38. It is important that travelers should be submitted to a surveillance on the part of the personnel of railroads, to determine their condition of health.

Article 39. Medical intervention is limited to a visit (inspection) with the taking of temperature of travelers, and the succor to be given *to those actually sick. If this* visit is made, it should be combined as much as possible with the customhouse inspection to the end that travelers may be detained as short a time as possible. Only persons evidently sick should be subjected to a searching medical examination.

Article 40. As soon as travelers, coming from an infected locality. shall have arrived at their destination, it would be of the greatest utility to submit them to a surveillance which should not exceed ten or five days, counting from the date of departure, the time depending on whether it is a question of plague or cholera. In case of yellow fever the period should be six days.

Article 41. Governments may reserve to themselves the right to take particular measures in regard to certain classes of persons, notably vagabonds, emigrants and persons traveling or passing the frontier in bands.

Article 42. Coaches intended for the transportation of passengers and mails should not be retained at frontiers.

In order to avoid this retention a system of relays ought to be established at frontiers, with transfer of passengers, baggage and mails. If one of these carriages be infected or shall have been occupied by a person suffering from plague, cholera or yellow fever, it shall be detached from the train for disinfection at the earliest possible moment.

Article 43. Measures concerning the passing of frontiers by the personnel of railroads and the post office are a matter for agreement of the sanitary authorities concerned. These measures should be so arranged as not to hinder the service.

Article 44. The regulation of frontier traffic, as well as the adoption of exceptional measures of surveillance, should be left to special arrangement between contiguous countries.

Article 45. The power rests with governments of countries bordering on rivers to regulate by special arrangement the sanitary régime of river routes.

ARTICLES RELATING TO YELLOW FEVER.

Article 46. Ships infected with yellow fever are to be subjected to the following regulations:

1. Medical visit (inspection).
2. The sick are to be immediately disembarked, protected by netting against the access of mosquitoes and transferred to the place of isolation in an ambulance or a litter similarly screened.
3. Other persons should also be disembarked if possible, and subjected to an observation of six days, dating from the day of arrival.
4. In the place set apart for observation, there shall be screened apartments or cages where anyone presenting an elevation of temperature above 37.6 degrees Centigrade shall be screened until he may be carried in the manner indicated above to the place of isolation.
5. The ship shall be moored at least two hundred meters from the inhabited shore.
6. The ship shall be fumigated for the destruction of mosquitoes before the discharge of cargo, if *possible. If a* fumigation be not possible before the discharge of the cargo, the health authorities shall order either:
    (*a*) The employment of immune persons for discharging the cargo, or
    (*b*) If non-immunes be employed they shall be kept under observation during the discharging of cargo and for six days, to date from the last day of exposure on board.

Article 47. Ships suspected of yellow fever are to be subjected to the measures which are indicated in Nos. 1, 3 and 5 of the preceding article; and, if not fumigated, the cargo shall be discharged as directed under subparagraph (*a*) or (*b*) of the same article.

Article 48. Ships *indemne* from yellow fever, coming from an infected port, after the medical visit (inspection), shall be admitted to free pratique, provided the duration of the trip has exceeded six days.

If the trip be shorter, the ship shall be considered as suspected *until the* completion of *a* period of *six days,* dating from the day of *departure.*

If a case of yellow fever develop during the period of observation, *the ship shall be considered as infected.*

Article 49. All persons who can prove their immunity to yellow fever, to the satisfaction of the health authorities, shall be permitted to land at once.

Article 50. It is agreed that in the event of a difference of interpretation of the English and Spanish texts, the interpretation of the English text *shall prevail.*

TRANSITORY DISPOSITION.

The governments which may not have signed the present convention are to be admitted to adherence thereto on demand; notice of this adherence to be given through diplomatic channels to the government of the United States of America and by the latter to the other signatory governments.

Made and signed in the City of Washington on the 14th day of the month of October nineteen hundred and five, in two copies, in English and Spanish respectively, which shall be deposited in the State Department of the Government of the United States of America, in order that certified copies thereof, in both English and Spanish, may be made to transmit them through diplomatic channels to each one of the signatory countries.

Dr. Eduardo Moore, Juan J. Ulloa, Juan Guiteras, E. B. Barnet, Emilio C. Joubert, M. H. Alcivar, Walter Wyman, H. D. Geddings, John S. Fulton, Walter D. McCaw, J. D. Gatewood, H. L. E. Johnson, M.D., Joaquin Yela, E. Licéaga, J. L. Medina, M.D., Daniel Ed. Lavoreria, N. Veloz Goiticoa.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Thirty-first Annual Meeting, held at Indianapolis, Oct. 10-12, 1905.

(*Continued from page 1354.*)

General Blood Poisoning Emanating from the Nose and Pharynx.

Dr. J. Holinger, Chicago, stated that micro-organisms of the nose and pharynx were formerly considered harmless. A great many diseases can be directly traced to them. Fatal cases of blood poisoning occur, but are not very frequent. With the decrease in the number of streptococci in the pharynx all general symptoms not only diminish, but disappear. The connection between acute rheumatism and tonsillitis is well known. The tonsil receives its lymph from the nose and pharynx, and may, therefore, become secondarily inflamed in cases of infections located in the nose and pharynx. There is a difference in the course of the disease, whether the infection dates from the nose and pharynx, or directly from the tonsils. The most striking example is diphtheria. Histories of cases are given by the author where chronic rheumatism of many years' standing, which had been treated with all kinds of medicine, massage and *x*-ray, disappeared when the suppurative processes in the nose and its sinuses were cured. The mixed infections of tuberculosis of the lung and bones may be avoided, in the opinion of the author, if the pharynx and nose whence they start are treated. As to treatment, very little is accomplished by sprays. Washes with boric acid solution are used in the nose, and in the pharynx paintings with solutions of iodin and iodid of potash and glycerin.

Cancer of the Rectum.

Dr. E. B. Smith, Detroit, made a special plea for extirpation in the treatment of cancer of the rectum as being the only procedure that will give hope of a cure. He spoke of colotomy as the operation of necessity rather than of choice, and urged examination in all cases where the rectum is involved, as in cases of hemorrhage, where there are bloody stools, where there is painful defecation, and where there is constipation, and advised a microscopical examination in all cases where the neoplasm is developed. The author shows that the extirpation of a part or the whole of the rectum by the Kraske method is the ideal operation, and should be practiced only by those who have had experience in capital operations.

Surgery of Visceral Injuries from Violence to the Abdominal Wall.

Dr. John Young Brown, St. Louis, called attention to the mortality in such cases, and emphasized the importance of their early diagnosis and prompt surgical treatment. He reported a series of six cases, in all of which abdominal resection was done. Of the six cases, one recovered and five died. An analysis of cases confirms the importance of early diagnosis and prompt surgical treatment by abdominal section in all cases of abdominal contusion in which there were present the slightest symptoms pertaining to injury to peritoneal viscera.

Intraperitoneal Tuberculosis.

Dr. F. F. Lawrence, Columbus, Ohio, drew the following conclusions: 1. Intraperitoneal tuberculosis is frequently a local disease. 2. It probably occurs much more frequently in the female than in the male. 3. In a large majority of cases it is primarily visceral and the general peritoneum is secondarily involved. 4. The surgical treatment is rational, sometimes agreeably surprising in results, and again bitterly disappointing. 5. In this, as in many other surgical conditions, early diagnosis and early operation will bring more certain results. 6. In this condition the greatest obstacle to overcome is the idea that it is a secondary condition. 7. No case of intraperitoneal tuberculosis should be denied the benefits of operation, no matter how extensive, as long as there is no positive pulmonary or pleuritic involvement, for the reason that some apparently hopeless cases fully recover. 8. When there is a tubercular peritonitis, a sequel of tubercular tubes, ovaries or appendix, the primary focus should always be removed. 9. In these tubercular cases the mesenteric glands have not been found frequently involved, and when they are operation accomplishes very little good. 10. In tubercle of tubes and ovaries the adhesions are usually firm, sometimes, though not usually, very vascular, and not infrequently involve loops of the small intestine; hence the greatest care is necessary to avoid serious injury to the bowel and at the same time separate completely all adherent surfaces and provide complete drainage. 11. Drainage is the great factor in recovery, when properly carried out.

Pyloroplasty with the McGraw Ligature.

Dr. J. Henry Carstens, Detroit, said that many cases with disturbances of digestion can not be diagnosticated or relieved by medication. These should be subjected to an exploratory celiotomy. Gastroenterologists should not treat patients for months and years if they can not make a positive diagnosis or cure a patient. After reasonable efforts the patient should be sent to the surgeon for relief. The McGraw ligature is a valuable means of relieving stricture at the pylorus and the resulting dilatation of the stomach. This method of operating is easy and quick; the danger is very small, and the operation is preferable to those heretofore used in benign contractions of the pylorus. It is a great deal better than gastroenterostomy, as one restores as nearly as possible the normal condition.

Ovarian Cystoma.

Dr. L. P. Luckett, Terre Haute, Ind., reported a case of ovarian cystoma on which he had operated. The tumor originated from the left ovary, was attached by a broad pedicle, which was tied off in sections. The uterus and right ovary were found to be normal. The fluid and tumor were estimated to have weighed between seventy and eighty pounds. The patient made an excellent recovery.

Closure of Vaginal Fistulae.

Dr. Maurice J. Rosenthal, Fort Wayne, Ind., said that a considerable area of scar tissue and vaginal mucosa may be inverted into the bladder without producing ill effects. Ureteral fistula embedded in scar tissue may be inverted into the bladder and continue to discharge its urine without becoming stenosed. Even large vaginal fistulæ, where part of the bladder walls are lost in scar tissue from a previous hysterectomy, may be successfully operated by denudation and suture through the vagina without disturbing the relations of the bladder or any adhesions of pelvic viscera which may have formed in the scar.

Sprained Ankle.

Dr. Robert Carothers, Cincinnati, drew the following conclusions: 1. No one is exempt from a sprained ankle, although some are more prone to it than others. 2. In severity a sprained ankle will range from a trivial accident to one of extreme severity and everlasting. 3. The outer side more often than the inner side of the ankle is the seat of trouble. 4. The diagnosis, which is ordinarily made with ease, is at times made with difficulty, and occasionally an *x*-ray examination is required to make the diagnosis certain. 5. The treatment by immobilization with a plaster-of-Paris cast is unsatisfactory and at times injurious. 6. That the treatment instituted by Coteral, the so-called adhesive plaster strappings, advising and urging the patient to walk on the injured foot, the early removal of these straps, followed by massage, gives the most satisfactory and best results. 7. That the old cases are to be, under anesthesia, converted into acute sprains and treated in the same manner.

Shall the Profession or the Laity be Responsible for the Death Rate in Appendicitis.

Dr. J. C. O'Day, Oil City, Pa., said that every physician, when confronted with a case of appendicitis, should frankly tell the patient the nature of his trouble; explain to him, honestly and candidly, the disposition of his disease; that no one can tell what an inflamed appendix will do, and that there is no safety till the offending organ has been removed. If the patient then decides to postpone operation, he, not the surgeon, should be responsible. If this were done, he thinks we would hear no more complaints of, "Why did not the physician advise operation before it was too late?"

Sarcoma of the Anterior Segment of the Globe.

Dr. O. Tydings, Piqua, Ohio, presented a brief history of a case on which he had operated for the removal of a melanosarcoma of the anterior segment of the globe. The diagnosis was confirmed by reliable microscopists and pathologists. Five days after the removal of the tumor the patient disappeared and the speaker did not see him again until the following August. There was no recurrence; the cicatrix is smooth; the lone pigmented spot, not larger than a pin-point, which the author takes to be the remains of an old hernia in the iris, is still present, but absolutely quiescent. The patient's vision, which, when he first saw him, was, right eye 20/40, and when operated 20/200, and left eye, 20/30, is now 20/20 in each eye. So far as the author has been able to examine authorities, the case stands alone.

The following papers were also read: "Bone Tuberculosis, with Report of a Case," by Dr. W. W. Vinnedge, Lafayette, Ind.; "Post-Operative Acute Dilatation of the Stomach, with Report of a Case Following Nephropexy," by Dr. A. E. Halstead, Chicago; "Treatment of Tuberculosis of the Cervical Lymphatics," by Dr. H. C. Sharp, Jeffersonville, Ind.; "Surgical Treatment of Nephritis," by Dr. A. H. Ferguson, Chicago; "Visceral Ptosis: Its Surgery," by Dr. Earl Harlan, Cincinnati; "The After-Treatment of Gastroenterostomy," by Dr. Charles A. L. Reed, Cincinnati; "Extraperitoneal Rupture of Bladder Complicating Fracture of Pelvis," by Dr. J. R. Eastman, Indianapolis; "Cysts of the Mesentery, with Report of a Case," by Dr. L. G. Boweds, Dayton, Ohio; "Perforating Ulcers of the Duodenum, with Report of a Case," by Dr. M. A. Austin, Anderson, Ind.; "Appendicitis," by R. E. Haughton, Richmond, Ind.

The papers mentioned above were read in the surgical section. In the medical section, over which Dr. Frank P. Norbury, Jacksonville, Ill., presided, the following papers were read and discussed:

The Present Conception of Bright's Disease.

Dr. G. W. McCaskey, Fort Wayne, Ind., said that the only possible justification for the use of the term is a historical one, and while its meaning must in a sense change with the changing views of pathology, yet the primary groundwork which constitutes the historical basis on which it stands should be kept constantly in view.

He presented a brief inquiry as to the character of the group of morbid states and symptoms originally described by Bright. In spite of the mutations of opinion and classifications, one can not but be impressed by the close resemblance between the views entertained to-day and those of half a century ago concerning what may be called the gross features of Bright's disease. The author divides the causal conditions into six classes: First, the acute infections; second, chronic infections; third, chemical poisons introduced into the circulation, of which lead may be taken as a type; fourth, the influence of cold; fifth, the products of perverted gastrointestinal function, and especially intestinal putrefaction; and, sixth, the products of perverted metabolism.

Treatment of Tuberculous Pleurisy with Effusion.

Dr. Theodore Potter, Indianapolis, presented the following deductions: 1. The profession has gone too far in accepting the general principle and following the general practice that pleural serous effusions, unless they show a tendency to early absorption, should be removed. 2. Granting that in the majority of such cases pleurisy is the dominant feature and removal of the fluid the proper procedure, and that such removal will probably tend to arrest the pleural tuberculosis, which is usually present, nevertheless the best results ought to be obtained by dealing with each case on its own merits. 3. In cases in which the pleurisy is the sole or dominant feature, the removal of the fluid is the proper treatment; and in proportion to the accuracy of differentiation between the pleural and the pulmonary disease will be the promise of good results by the removal of an effusion. 4. In cases in which the tuberculosis of the lung is evidently or probably the overshadowing feature, a conservative course as regards the removal of a serous effusion is the proper one. In some cases the fluid had best be left to Nature to take care of, with the hope that the compression, immobilization, and physiologic quietude of the tuberculous lung may tend to arrest the disease. In other cases of this type the removal of the fluid should be undertaken only after due consideration.

Tuberculosis in General Practice.

Dr. Hugh A. Cowing, Muncie, Ind., said that the general practitioner should exercise great care in physical examination. He should strive to make an early diagnosis. He should carry a life-saving knowledge into the tuberculous home; improve its hygiene, and teach sanitation. He should employ the pure air treatment, the method varying according to the individual case. He should co-operate with health boards and report cases. He should estimate the cost before sending a patient to a health resort. He should study health resorts and sanatoriums, and visit them, if possible. He should oppose quack consumption cures, and quack doctors who "cure consumption." He should influence the press for sanitation. He should fight patent medicines. He should expose christian science and kindred fads that rob the consumptive of his chance for life. He should endeavor to seek legislation for sanitary advancement. He should help to popularize the consumptive sanatorium health farm. Membership in a society for the prevention of tuberculosis will make the physician's work more effective.

Management of Neurasthenics.

Dr. H. A. Rodebaugh, Columbus, Ohio, said that an individual becomes neurasthenic only after having suffered from some of the psycho-neuroses, the latter having been caused by traumatism, by disturbed metabolism, or by peripheral nerve irritation. Heredity, occupation or environment can hardly be considered etiologic factors without further specification. Neurasthenia should be considered a mental rather than a physical disease. Mental symptoms often persist after the removal of all physical causes, and can only be relieved by psychic treatment. Mental hygiene is both preventive and curative. The neurasthenic should be taught that a healthy mental attitude conduces to bodily health.

Autointoxication.

Dr. D. L. Field, Jeffersonville, Ind., said that the part played by the intestinal emunctories in the elimination of certain poisonous substances is attested by the commonly fetid stools of persons who frequent postmortem examinations. The fetid character recalled the putrid odor of emanations from the cadaver. If poisonous products have been absorbed, an effort should be made to destroy them. The liver has the power of arresting poisons. One should, therefore, stimulate its action by proper therapeutic measures. If the poisons have escaped the liver they should be eliminated by the skin, the lungs, the intestines and the kidneys. If all these attempts fail one should have recourse to certain antidotes which tend to counteract the physiologic effects of the poisons which menace the system. As a striking example, he mentions the antagonistic properties of poisons in atropin and pilocarpin. The strength of the patient should not be neglected, so that he may have time to eliminate the poisons.

Pathology of Epilepsy.

Dr. Marc Ray Hughes, St. Louis, shows that each epileptic stage has a distinct pathology, and the entire category for classification of epilepsy, including the psychical varieteis, has one common pathology or gross structural change, and that this structural change, whether idiopathic or organic, has to do largely with the movements of the centrifugal and centripetal mental forces as they are found in the psychical equivalent of epilepsy—dual consciousness, obliviousness and allied states of mental eclampsia.

History and Treatment of Epilepsy.

Dr. John W. Selman, Greenfield, Ind., said that epilepsy and other diseases may exist together, and for this reason the prognosis and diagnosis are to be carefully reached and given. Jan. 2, 1905, a man, 28 years old, was brought to him, who was having epileptic seizures five and six times a week. There was no aura. Like a flash he was in hard convulsions. The general appearance of the patient indicated great anemia, malnutrition, with diarrhea. The author used subcutaneous injections of normal saline solution, with the bitter tonics and arsenic, and at the expiration of ten days a great change in his condition was noticeable, and in three months he returned home apparently well. The treatment should consist in the removal of any exciting cause, in the checking of the convulsive tendency, and in the prevention of any further attacks. The treatment is medicinal or operative, according to the causal factors.

The Cigarette; Its Relation to Mental and Nervous Diseases.

Dr. W. B. Fletcher, Indianapolis, quoted extensively from articles by physicians and prominent laymen on the cigarette habit, and said that he has sometimes asked himself if the members of the medical profession are not largely responsible for the widespread prejudice against the cigarette. It is so much easier to agree with the grief-stricken mother in assigning the cause of the loved one's downfall to the innocent habit of cigarette smoking, than to tell her the real cause which examination has revealed, or which has been imparted under the seal of professional confidence. In the past twenty-two years he has examined over 1,200 cases of nervous disease and insanity where the cause of the malady was given as the cigarette habit. In not one case has he reason to believe that tobacco had anything to do with the causation of the disease. They were all young men, and some of them were insane without doubt. Some of them smoked cigarettes to excess, but their insanity is only a cause of their excess, and not the excess the cause of the insanity. Many of them were simple cases of hebephrenia, with a cigarette attachment, so to speak. One boy, 16 years of age, and at the time in acute mania, had been severely punished by his father to "beat out the cigarette habit." After three months he recovered and proved to be an unusually bright and truthful boy. He acknowledged that he had smoked three cigarettes in his life, just before his mind gave way from overwork in the harvest field. Some of the cases were tuberculosis of the brain, but Dr. Fletcher thinks he is safe in saying that fully 90 per cent. were young fellows reared in idleness, who had acquired other habits which were reducing their vitality and sapping their brain, and the cigarette was used as a cover by the patients, parents and friends, or as an excuse to hide their shame.

The Tonic Alterative Action of Copper and Arsenic in Primary and Second Spanemic States.

Dr. George F. Butler, Chicago, said that arsenic has a very decided action on tissue change and markedly affects the glandular, nervous, respiratory and cutaneous systems. Copper is reputed to be a violent poison, yet, except so far as its toxic effects as a foreign body in the eye are concerned, this repute is decidedly undeserved. Copper is *recommended as an alterative* tonic useful in epilepsy, chorea and other spasmodic conditions, especially those connected with debility, by the older authors, and later therapeutists sustain this old repute of copper. Several authorities were quoted by the essayist to the effect that this drug, in small doses, stimulates both the heart and the capillary circulation, and is a general nerve tonic. As to the preparation to be employed, all agree that while copper sulphate is of value, it has *at times* unexpected dangerous untoward effects when the point of saturation is reached. These effects, through the influence of the drug on the vascular system, often take the direction of cardiac neuralgias and pseudo-anginas. The double salts of copper in small doses exert a cardiac action similar to that of digitalin, strophanthus, helleborein, etc. Hare prefers copper arsenite. He has found that under its use digestion and nutrition improve. It is superior to Fowler's solution in chorea and similar neuroses. In toxemic conditions, like secondary malarious manifestations, with the resultant pallor, copper and arsenic are of decided value. Cases in which the periodic tendency has disappeared improve decidedly under copper and arsenic, whereas quinin and iron are worse than useless. The influence of arsenic is very marked on chronic rheumatism and so-called rheumatic gout, neuralgias of various sorts, in tic, and hemicrania, as well as in angina pectoris, chorea, epilepsy and asthma. *In certain* of the *gouty bronchites*, at the *onset of* phthisis, in imperfectly cleared-up pneumonic lung consolidation, arsenic acts sometimes with remarkable efficiency. The influence of both drugs on the liver, whose double functions are so necessary to the tissue changes of the system, show that both play a part in assisting assimilation and at the same time destroying waste products.

The Claims of the Adolescent.

DR. FRANK P. NORBURY, Jacksonville, Ill., stated that the claims of the adolescent for recognition by the medical profession, are genuine, not hypothetical, and involve three important considerations: 1. Physiologic—a study of growth, development, sex differentiation. 2. Psychologic—normal and morbid, involving honest endeavor of the physician to see the real needs of the individual. 3. Pedagogic—training and treatment to go together. All these considerations show that a demand exists for qualified men to consider earnestly the problems of mind and body of this period.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Annual Meeting, held in Scranton, Sept. 26-28, 1905.)

(Continued from page 1351.)

Ectopic Gestation.

DR. CHARLES P. NOBLE, Philadelphia, stated that during the past 16 years he has operated on 91 patients; 89 by abdominal section and 4 by the vaginal route, two of the latter subsequently requiring abdominal section. In 44 of these cases the pregnancy was in the left tube; in 40 in the right; in 7 the report did not show which tube was involved. The causes are usually mechanical, due either to infection or congenital defects of the tube. The ideal time for operation is before rupture, and should consist of the removal of the involved tube with or without the ovary. Early diagnosis and prompt operative interference were urged as important factors. Careful consideration of the history greatly facilitates the diagnosis.

DISCUSSION.

DR. GEORGE D. NUTT, Williamsport, reported two cases of rupture occurring in the broad ligament and also a case in which a rupture of the right tube containing a quantity of blood had been completely walled off from the abdominal cavity, the menstrual periods being regular for seven months prior to the operation.

DR. J. C. O'DAY, Oil City, mentioned as diagnostic symptoms a history of sterility without apparent cause, with sudden cessation of the menstrual periods and pelvic pain. Among the causative factors were mentioned gonorrhea, torsion of the tubes and other mechanical factors, he reported a case in which an operation for a cystic ovary revealed a ruptured extrauterine pregnancy in the left tube which was completely walled off.

DR. FRANKHLIN F. ARNDT, Scranton, recommended as a diagnostic aid curettage and examination of the scrapings for decidual cells.

DR. NOBLE, in closing referred to cases in which the pain was in the epigastrium and temperature above normal even after considerable hemorrhage had taken place. He felt that spontaneous recovery undoubtedly takes place in a number of cases, but, of course, it is not within the power of the physician to tell just which these cases will be; hence, operative interference must be resorted to in all cases. Where there is a history of missed period, pelvic pain and the finding of a mass, a diagnosis of extrauterine pregnancy will in 99 cases out of 100 be correct.

The Restitution to Normal After Childbirth.

DR. BARTON COOKE HIRST, Philadelphia, stated that injuries of the genital canal and backward displacement of the uterus constituted more than one-third of over 6,000 cases of diseases of women that had come under his observation, and, if to this number are added the puerperal infections, pelvic inflammations, abortion, subinvolution, endometritis and other pathologic consequences of parturition, they would constitute far the larger proportion of cases. Among the remainder would be a limited number of neoplasms, genital tuberculosis and gonorrhea. He urged the establishment of hospitals in connection with medical colleges, in order that the students might be taught the practical as well as the theoretical side of obstetrics. The patient should be carefully watched during the period of gestation and parturition, and a sufficient number of examinations made afterward to insure the physician that all the organs have returned to normal.

DR. GEORGE M. BOYD, Philadelphia, stated that, except in cases of excessive bleeding and injury to the broad ligaments, the cervix should not be repaired immediately after childbirth, but the reverse is true in regard to injuries to the perineum, as better results are secured from immediate repair, except where the patient is in a very exhausted condition. He urged careful watching over the patient during pregnancy and careful examination after childbirth to satisfy the attendant that the genital tract had returned to normal.

Uterine Curettage.

DR. E. E. MONTGOMERY, Philadelphia, stated that the indications for the use of the curette are chronic endometritis; polypoid or mucous growths projecting from the mucous surface of the uterine cavity; retrodisplacements if followed by measures to restore the normal position; pelvic inflammation, if associated with measures to correct the intraperitoneal disorders; carcinoma for the purpose of securing scrapings for study, and the retention of products of embryonic life. The conditions cited as contraindications were: acute endometritis, intrauterine myomata, or any other cases in the absence of intrauterine inflammation. Aseptic precautions should be observed in the preparation of the operator, the patient and the instruments. Pratt's dilators and metal bougies were recommended. The operation should be performed only by one skilled in the work, and drainage is essential.

Significance and Management of Chronic Uterine Hemorrhage.

DR. GEORGE ERETY SHOEMAKER, Philadelphia, stated that the determination of whether or not the flow is normal can only be made by comparison with the other periods of the same individual during a time when she was in a healthy condition. He cited, among the causes for hemorrhage, passive congestion of the pelvic vessels, pelvic disease outside of the uterus, prolapsed and cystic ovaries, chronic adherent inflammatory disease, disorders of pregnancy, partial placenta previa, threatened abortion, and extrauterine pregnancy. He deprecated the idea that preceding the menopause there was likely to be slight hemorrhage, and urged careful examination and prompt treatment of all cases.

DISCUSSION.

Dr. Richard H. Gibbons, New York, reported a case in which, after he had done a curettement and employed a bichlorid solution of 1 to 3000, he opened the abdominal cavity to complete the operation and found the intestines blistered, which could only be explained by the escape of fluid into the abdominal cavity. He considers the curette a dangerous instrument, except in experienced hands, and reported cases illustrative of this point.

Dr. Charles P. Noble, Philadelphia, emphasized the importance of educating the laity to know that hemorrhage preceding the menopause is not a natural factor and calls for thorough examination, which he believed would be valuable in reducing malignant disease. He called attention to the necessity for accurate diagnosis before the employment of the curette and deprecated its use to assist in diagnosis, except to secure scrapings for examination in malignant disease.

Dr. George M. Boyd, Philadelphia, deprecated the use of the curette following miscarriage or abortion. He believes that the finger is better able to empty the uterus. In an experience of 15 years at the Philadelphia Lying-in Charity, covering over 10,000 cases, he never found it necessary for that purpose.

Dr. J. M. Baldy, Philadelphia, believed that the curette was a valuable instrument in properly selected cases, and felt that the best method of dilatation was by means of the forceps, as it was thus necessary to make but one insertion, minimizing the danger of injury to the genital tract.

The Technic Employed in One Hundred Laparotomies.

Dr. L. J. Hammond, Philadelphia, reported 100 cases, 36 with localized pus and 64 in which pus was absent, consisting of appendicitis, cholelithiasis, etc., with but four fatalities, one of which was drained. He expressed the opinion that drainage should only be instituted when there is some positive indication for it, although in cases of disease of the gall bladder drainage should always be employed.

Dr. J. G. Clarke, Philadelphia, stated that as the number of operations became greater the number of times which drainage was employed decreased. He believes that drainage should be the exception rather than the rule.

Dr. J. Montgomery Baldy, Philadelphia, believes that the less the abdominal contents are handled the better, and that the more experienced the operator became the less he would employ drainage.

Dr. Ernest Laplace felt that drainage should not be employed unnecessarily, but in cases of doubt it is better to drain.

Management of Pus Cases in Abdominal Surgery.

Dr. Reed Burns, Scranton, stated that in empyema of the gall bladder the best results followed cholecystectomy, and in cases of pyosalpinx, suppurating ovaries and tubes, ovarian abscesses, suppurating cysts and acute salpingitis, operative procedure is the method of choice. In appendiceal abscess he recommended that the pus be evacuated before opening the abdomen. Before closing, the wound should be flushed and drainage established if necessary.

DISCUSSION.

Dr. W. L. Estes, South Bethlehem, felt that the reason drainage did not produce the results expected was because of improper method. In some cases an important factor, particularly with women, is the raising of the head of the bed.

Dr. J. C. O'Day, Oil City, said that the gall bladder should be left in and drained whenever possible owing to the danger of fibrous degeneration and closure of the common duct.

Dr. William L. Rodman, Philadelphia, did not favor the flushing of the abdominal cavity when the pus was confined to a limited and circumscribed area. Cholecystectomy should be confined to cases of gangrene or other disease of the gall bladder.

Dr. Richard H. Gibbons, New York, urged the necessity for immediate operation in all cases of appendicitis and stated that the appendix should be taken out whenever a laparotomy is done. In regard to the gall bladder it had better not be removed unless malignant degeneration is present.

Dr. Charles P. Noble, Philadelphia, said that drainage should be employed only when especially indicated. It is better to remove the source of the infection and then pack with sterile gauze than to flush out the abdomen in cases of free pus and general peritonitis.

Cancer of the Head and Neck.

Dr. George W. Crile, Cincinnati, Ohio, presented a detailed report of 128 operations on 110 cases. He believed that the same method of procedure should be instituted in these cases as is followed in removal of cancer in other portions of the body, sufficient tissue being removed to insure the destruction of all the infected glands.

Dr. R. H. M. Dawbarn, New York, recommended complete extirpation of the growth, even removing a portion of the deep jugular vein if involved, and, in order to avoid tying vessels as much as possible, suggested the cording, first, of the lower extremities for ten minutes and then the upper extremities. For the purpose of keeping infection from the lungs, the foot of the bed should be raised and the patient not allowed to sit up until he can do so and drink a glass of water without coughing. If the patient becomes exceedingly weak during the operation, it may be necessary to discontinue it temporarily for a few days or a week, to be finished as soon as the physical condition of the patient will permit.

A New Intestinal Bobbin.

Dr. John G. Clarke, Philadelphia, reported his experiments with this device on dogs and illustrated its practical application on an imitation intestine. He called attention to the ease with which the parts could be separated after the suture was made, and claimed as one of the most important points in favor of the bobbin the shortening of the time required for the operation.

DISCUSSION.

Dr. William L. Rodman, Philadelphia, said that whenever possible mechanical devices should be done away with, but felt that the bobbin presented was superior to the Murphy button, as it was less likely to cause intestinal obstruction. He believed that it would be of value in end-to-end anastomosis.

Dr. R. H. M. Dawbarn, New York, also considered the device superior to the Murphy button and expressed his intention of trying it in posterior gastroenterostomies, which he felt to be about the only cases in which the use of the mechanical devices is justifiable.

Dr. Reed Burns, Scranton, prefers the suture, except in cases of end-to-end anastomosis, in which he has found the Murphy button quite satisfactory.

Dr. J. C. O'Day, Oil City, felt placing the ends of the intestine in perfect apposition accomplished the desired result, no matter what means might be used to attain that end. While not favoring the free use of mechanical devices, he believed there were cases in which nothing but the Murphy button would give satisfactory results.

Dr. Edward Martin, Philadelphia, attributed the preferences for the different mechanical devices in large measure to the experience of the individual operators, but believed that sutures would continue to be the most generally used.

Wandering Gallstones.

Dr. William L. Estes, South Bethlehem, stated that cases of indubitable perforation of the gall bladder are comparatively rare. If the ulceration is slow, and the patient survives the first septicemic condition, the stones will burrow in the direction of the least resistance and may be found in almost any part of the posterior portion of the abdomen. Prominent symptoms are severe pain, tumor, disturbance of gastric and inetstinal function, jaundice, present only in the early stages or absent entirely, with general symptoms of septicemia.

Surgery of the Gall Bladder and Ducts.

Dr. J. Montgomery Baldy, Philadelphia, stated that in many instances too radical treatment has been instituted. He reported, as illustrative of this point, a case in which the gall bladder and part of the cystic duct were removed, after which the patient's condition cleared up and remained so for about a year, when she again returned to the hospital with the same symptoms as before. Another operation was done and intestinal adhesions broken up. Five months later she again returned suffering from jaundice and the other symptoms. After rest in bed for a couple of weeks, without operation, the symptoms disappeared. He believes that the gall bladder is too frequently removed on slight symptoms.

Dr. Walter S. Stewart, Wilkesbarre, urged the removal of gallstones from the bladder and the establishment of drainage. He reported a case in which, while operating for ventral hernia, he incidentally examined the gall bladder and common duct and found stones in both. In another case, diagnosed as appendicitis, the pus cavity was merely drained, and afterward the patient suffered from jaundice a number of times, and it was decided that it was due to gallstones.

Dr. Chas. P. Noble, Philadelphia, reported two cases of wandering gallstones, one of which gave a history of gallstone colic, rendering the diagnosis easy. In the other case, on operation, the stone was found between the stomach and gall bladder.

Decompressive Operation in Inoperable Brain Tumors.

Dr. Harvey W. Cushing, Baltimore, Md., referred to the various methods employed for accomplishing this result and stated that the bone should not be removed entirely, as, if it was, in a short time there would be a protrusion through the opening which frequently resulted in paralysis of a more or less extensive type. The chief end to be attained is to relieve the pressure and still leave some sort of a covering to keep the brain within the cranium. The most favorable position for the operation is the intramuscular temporal region.

Dr. R. M. Dawbarn, New York, believes that it is best not to remove the bone entirely, but to prevent the edges growing together by placing a piece of non-irritating tissue between them. Where he finds it necessary to remove the bone, he covers the opening with a specially prepared celluloid, which will not be absorbed, is a non-irritant and forms a protection against trauma.

Dr. Samuel Kay, Scranton, presented a case of supposed inoperable tumor of the brain occurring in a child of 7 years of age. There was extreme exophthalmos, polyuria and other gross pathologic changes, all of which had appeared within three years. Some months ago the quantity of urine passed in 24 hours was 27 quarts. At present it is about 23 quarts, with a specific gravity of 1000 to 1001. There is no specific history, and the child was perfectly well until 4 years of age. Now there can be felt an opening on each side of the skull, on the right about 6 cm. by 9 cm. and on the left about 5 cm. by 7 cm.

Dr. Cushing stated that it would be impossible to diagnose the condition of the case exhibited without having more of the facts and studying it more closely. Although he felt it quite probable that it was a tumor of the auditory centers with resultant nutritional changes and pronounced exophthalmos. He particularly urged the value of decompression as a palliative measure, but did not favor the insertion of celluloid or any other foreign substance.

Direct Fixation of Fractures.

Dr. John B. Roberts, Philadelphia, while believing that in ordinary instances outward appliances were sufficient, referred particularly to the extraordinary cases and discussed in detail the various methods employed for this purpose, including wires, catgut, bone ferrules, metallic plates, etc. He stated that for transcutaneous fixation he had at first used ordinary wire nails, but afterward devised a surgical nail with a sharp point. For the open fractures or closed fractures which have been explored better results will ensue from the use of staples or plates.

Dr. George W. Guthrie, Wilkesbarre, stated that his experience with direct fixation had been chiefly in cases of delayed union, and that he preferred an end-to-end fixation and the insertion of a silver wire which could be allowed to remain.

Dr. Chas. E. Thompson, Scranton, reported several cases of direct fixation and referred particularly to one in which a fracture of the femur was united by means of a wire nail and the man became able to walk around. It was supposed that union had taken place, but at his death, eighteen months later from another cause, autopsy revealed the fracture ununited.

Dr. DeForest Willard, Philadelphia, believes that direct fixation should be employed in all cases where it is necessary in order to bring the fragments of the bone into direct apposition.

Dr. John S. Niles, Carbondale, referred to the fact that in the mining regions many of the cases are not seen until several hours after the injury, when they were in a very unsanitary condition. The surroundings are equally unsanitary, and in only rare instances can operation be performed under aseptic conditions.

Dr. R. H. M. Dawbarn, New York, stated that in the cases referred to by the last speaker he would wait for twenty-four to forty-eight hours before effecting a union, in the meantime disinfecting the wound by means of bichlorid of mercury, etc.

Dr. Roberts suggested that direct fixation immediately following an injury might in some instances prevent bony union by causing bone necrosis.

How May the Scientific Meetings of the County Societies be Made More Profitable?

Dr. Theodore Diller, Pittsburg, urged that the proceedings be such that they incite every member to active interest; the meetings should be held at least once a month; there should be a special committee on scientific program; three or four papers, of 10 to 20 minutes each, are best for each meeting, and the officers should always be ready with substitutes, so that there may be no failure of a program. The subjects should be varied, the medical topics being discussed more frequently than the surgical. Symposia are of value occasionally, as are also presentations of cases and specimens. He urged more frequent meetings, stating that there are only two county societies that hold bi-weekly meetings and only twenty hold monthly meetings.

Dr. Franklin F. Arndt, Scranton, stated that the membership of the Lackawanna County Medical Society had increased during the last two years from 74 to 130, and that they are now making an effort to conduct their meetings along the line of the suggestions made by Dr. McCormack. Their scientific papers are provided for by a committee of 24 members, two of whom are responsible for the papers for each meeting.

Dr. Chas. A. E. Codman, Philadelphia, referred to the inauguration of the branch system in that city, and stated that, as each of the five branches held one meeting a month and the central society two meetings a month, it amounted to practically seven meetings a month for that society.

The Question of Lowered Gastric Secretion.

Dr. Chas. G. Stockton, Buffalo, stated that he had been prompted to bring this matter before the society by the increased number of gastroenterostomies and the belief of some that the stomach as a digestive organ could be dispensed with, the food being digested in the intestinal canal, in which, however, he did not agree. He stated that there is an important relation existing between the gastric secretion and the motor functions of the stomach, and also between the gastric secretion and the secretions of the pancreas, liver and intestines. Lowered gastric secretion, he said, is the expression of the following pathologic processes: 1. Acute and chronic inflammatory states of the gastric mucosa. 2. Atrophy of the gastric mucosa. 3. General or systemic functional depression. 4. Gastric neurosis. 5. Congenital peculiarity. He discussed in detail the effect of this condition in malignant disease, anemia, etc. Referring to treatment, he mentioned careful regulation of the diet and regular feeding. He stated that it is better to perform gastroenterostomy than to subject the patient to continued food stagnation, but believed gastric secretion would more nearly return to normal after pyloroplasty.

Surgical Treatment of Cardiospasm.

Dr. Edward Martin, Philadelphia, discussed the various causes of the condition and stated that it was more common than was formerly believed. Among the common symptoms is stoppage of food just below the ensiform cartilage. Great care must be observed to distinguish it from obstruction or compression stenosis, the history being of great importance in diagnosis. The palliative treatment consists of keeping up nourishment by means of a stomach tube. The operative treatment consists in divulsion of the sphincter. A case was reported in which palliative treatment had been carried on for some months without any effect, when an operation was done, and the patient made a good recovery.

Gastroenterostomy; Indications and Technic.

Dr. William L. Rodman, Philadelphia, defined the operation as being the means of opening the connection between the stomach and some part of the intestines so as to bring about emptying of the stomach, speaking particularly on the subject of gastrojejunostomy, which he stated was practically the only operation performed at the present time. He stated that the anterior method, while easier to perform than the posterior, had certain objectionable features, prominent among which was the length of the loop and the consequent liability of the occurrence of the vicious circle.

DISCUSSION.

Dr. James Tyson, Philadelphia, stated that his experience with this operation had been limited to two cases. The first was a woman, aged 50, who had been suffering for three days prior to the operation from a very severe hemorrhage supposed to be due to gastric ulcer. After three years she had another series of gastric hemorrhages of the most profuse type. A gastroenterostomy was done. Forty-eight hours after the operation she became delirious and died within twenty-four hours. The second case also showed symptoms of gastric ulcer, for which gastroenterostomy was performed, which was followed by the vicious circle. A second operation was done, which was followed by recovery. These two cases, he felt, illustrated the justification of operative interference in cases of gastric ulcer.

Dr. John B. Roberts, Philadelphia, felt that there was no doubt that the earlier these cases came to the surgeon the more favorable would be the prognosis. By educating the general practitioner to more accurate and earlier diagnosis the mortality will be decreased.

The following papers were also read: "Essentials of Successful Radium Therapy," by Chas. L. Leonard, Philadelphia; "Adjustment of Radiation for Various Physiological Effects," by Russell H. Boggs, Pittsburg; "Three Cases of Meningocele that Recovered," by G. W. Guthrie, Wilkesbarre; "Treatment of Empyema, with [illegible] Irrigation of the Pleural Cavities," by P. Y. [illegible]; "Neglected Incomplete Rupture of Perineum [illegible] C. DaCosta, Philadelp[illegible] Chas. H. Ott, Sayre; "Benign Stenosis of [illegible] [illegible]sm and Abdominal Adhe[illegible]; "Symptoms and Diagnosis of Cancer of [illegible] Gilbride, Philadelphia.

NORTH BRANCH PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, held Sept. 19, 1905.

The President, Dr. A. Bern Hirsh, in the Chair.

Important Changes in the Pharmacopeia.

Dr. E. Q. Thornton detailed changes in names, strength, dose, etc.

The Medical Chemistry of the Pharmacopeia.

Dr. Henry Leffmann discussed the use of the Pharmacopeia to the physician, to the analytical chemist and to the druggist, and felt that one effect of giving the dose of the various remedies would be to encourage the putting up of medicines by druggists without a physician's prescription. One point he viewed with disfavor was the adoption of an atomic body based on the hydrogen one system, instead of the oxygen 16 system, which he viewed as particularly unfortunate because of the fact that the oxygen 16 system was the one on which all the statistics of the Bureau of Agriculture were furnished. Another point which he viewed with disfavor was the introduction of a large number of manufactured substances, or substances made by the combination of other drugs. He objected to the use of the genitive case for the names of chemical solutions, such as carbonate of soda, and traced the origin of these terms from the French language in the latter part of the eighteenth century. He referred to the unnecessary complications caused by the distinction between ordinary water and distilled water and the test for nitrites in distilled water, which he said was of such a delicate nature that it was not practicable, particularly with the general practitioner. He particularly deprecated the introduction of the liquor antisepticus and headache powders, but commended the changes from hydrochlorate to hydrochlorid, and the changes from naphtol and naphthalin to betanaphtol and naphthalene.

DISCUSSION.

Dr. Henry S. Wieder referred to the difficulty of the physician becoming associated with the changes in strength, etc., by the new Pharmacopeia, and asked what method was adopted for informing them in this direction.

Dr. Frank C. Hammond referred to a case in which he had ordered tincture of lobelia, writing his prescription in accordance with the new edition, which produced severe and persistent vomiting, and on inquiry, he learned that the druggist had filled it according to the old Pharmacopeia.

Dr. W. Hershey Thomas asked which method would be pursued by the druggist in filling prescriptions given before the new Pharmacopeia was adopted.

Dr. Ellis E. Given stated that he had been informed by a druggist that he had filled all prescriptions dated before September 1, according to the old Pharmacopeia, including renewals put up after that date, and that all prescriptions subsequent to that would be put up under the new Pharmacopeia.

Dr. A. Bern Hirsh stated that he had been informed by a druggist in his vicinity that he intended to use the system outlined in the 1890 Pharmacopeia for some time to come. He felt that the change had been sprung on the profession too suddenly and that mention should have been made of it, and notice given through the prominent medical journals in order to permit the physician to familiarize himself therewith.

Dr. Henry Leffmann, in speaking of the criminal liability of druggists not compounding prescriptions according to the U. S. Pharmacopeia, referred to a decision of the Supreme Court of Ohio in a prosecution brought after the 1890 revision of the Pharmacopeia had come out in 1893. It was decided that an act of the legislature could have no reference to an edition of the Pharmacopeia published after the act was passed, and therefore the conviction could not be sustained.

Dr. E. Q. Thornton stated that he felt the reason that the Pharmacopeia was so little representative of the medical profession was because so few of the physicians appointed attended the convention for revision. In regard to the changes he stated that it must be remembered that it becomes necessary to throw out obsolete drugs and the only way he knew for physicians to become familiar with the Pharmacopeia was to have it in their libraries. He stated that Bulletin No. 23, recently issued by the Treasury Department, Marine Hospital Service of the United States, entitled "Changes in the Pharmacopeia," is of much value. The mere fact that a drug is mentioned in the Pharmacopeia, he said, does not necessarily signify, either that it is of value, or that it is endorsed by those engaged in the preparation of the work, but that there is a demand for it.

Dr. A. Bern Hirsh suggested the advisability of separating the drugs from the combinations and inserting them under separate headings. He also felt that in future revisions it would be best to have at least one-half of the committee consist of active practitioners.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Gastric Ulcer.

Merck's Archives quotes from Friedenwald's article on the medical treatment of this disease. The patient should be put at rest in bed for from two to five weeks, depending on the severity of the symptoms. The patient should also be kept strictly on a liquid diet mainly of milk. The rest in bed and rigid diet assist in the healing of the ulcer, guard against perforation and hemorrhage and, because of the lessened amount of nourishment required, the diseased stomach is not too severely taxed. The author then describes the diet and other treatment in detail: First, milk with lime water, gradually reaching from one to two quarts in twenty-four hours; then strained barley or oatmeal, broth clear or with broken-up egg; then a soft diet, such as rice cooked in milk, milk toast, or soft boiled eggs. At the beginning of the fourth week solid food may be given in the form of raw scraped beef, stewed chicken, boiled sweetbreads, baked potatoes, etc. Hot poultices are applied to the abdomen for several weeks during the early part of the treatment and from 200 to 300 c.c. of hot Carlsbad water are taken morning and evening. In the severe types of ulcer which are accompanied by excessive nausea, vomiting especially of blood, and pain, no nourishment should be given by mouth for from five to ten days. During this time the patient is fed by nutrient enemata. Bits of crushed ice may be allowed to aid in allaying the thirst. According to the recent investigation of Boas in cases of ulcer, small, invisible hemorrhages frequently occur, which can be detected only by special chemical examinations (the guaiac or aloin tests) of the fecal discharge. By means of these examinations for "occult hemorrhages" one is enabled to establish the individual term of treatment, dismissing the patient only when repeated tests fail to disclose further occult hemorrhages. An exclusive milk diet is objectionable because it does not successfully combat the anemia. For this reason Fütterer recommends the juice expressed from five pounds of beef to be taken daily to combat this condition. Lenhartz, too, has recently cautioned against the strict abstinence diet in the treatment of ulcer, even in those instances in which there is hemorrhage. He bases his conclusions on the fact that since ulcer of the stomach is frequently accompanied by superacidity and also by a generally enfeebled condition, it is best to give proteid food early to overcome the acidity as well as to build up the system. He gives eggs and milk ice-cold and in teaspoonful doses, raw scraped beef, zwiebeck, raw ham, butter, sugar, milk cooked with rice. In the mild cases of ulcer of the stomach the author recommends an ambulatory form of treatment. The patient is permitted to take only liquid or semisolid food and is then given one of the three following methods of treatment:

1. Nitrate of silver is prescribed in a solution of 1/6 to 1/3 gr. (.01-.02) doses for a period of three weeks.

2. Bismuth subnitrate may be administered in large doses (one teaspoonful) three times a day. Fleiner recommends giving it suspended in water, after previous lavage of the stomach. After the stomach has been thoroughly cleansed, from 10 to 20 gm. (ʒiiss to ʒv) of bismuth subnitrate, suspended in from 100 to 200 c.c. (℥iiss to ℥vii) of water, are passed into the stomach through the tube, after which the patient is required to lie on his right side for half an hour. In those instances in which there is any contraindication to the use of the tube Fleiner advises the administration of 10 gm. (ʒiiss) of bismuth subnitrate suspended in a glass of water in the morning before breakfast.

3. The oil cure has been recently recommended by Cohnheim in the treatment of ulcer of the stomach. Olive oil is taken three times daily from half to one hour before meals, in wineglassful doses in the morning, and in dessertspoonful doses at noon and in the evening. In very mild cases an emulsion of sweet almonds may be substituted for the oil. The oil fulfills several indications. It forms a coating over the stomach and thus assists in overcoming pylorospasm, and by relieving friction it overcomes pain; it checks the excessive secretion of acid, and improves the general nutrition. The treatment of a number of special symptoms is referred to.

SPECIAL SYMPTOMS.

Hemorrhage.—In all cases of hemorrhage, absolute rest in bed must be insisted on; an icebag should be placed on the epigastrium and a hypodermic injection of morphin administered. Hypodermic injections of ergot or gelatin—100 gm. (℥xxvi) of a 2 per cent. watery solution may be used. Recently Einhorn has recommended the hypodermic injection of a syringeful of adrenalin chlorid, 1 to 2,000 twice daily, or the internal administration of 15 drops of the same solution three times daily. In cases of great weakness or actual collapse from hemorrhage, saline infusions must be resorted to.

Acidity.—For the relief of the acidity, which is a usual accompaniment of ulcer of the stomach, it is frequently necessary to administer alkalies alone or combined with belladonna or codein.

Constipation.—This symptom may be relieved by the use of enemata or by the internal administration of oil or Carlsbad water.

When is an ulcer healed? may be answered in the affirmative when there is an entire absence of pain after taking solid food; when there is no longer pain on pressure in the epigastric region, and, finally, when repeated tests fail to reveal further "occult hemorrhages" in the fecal discharge.

INDICATION FOR SURGICAL TREATMENT.

1. Perigastric adhesions accompanied by tumor formation.
2. Hemorrhages which are very profuse, occurring at short intervals, or even small frequent hemorrhages which are not relieved by medical means.
3. Persistent nausea and vomiting, which is not relieved by the rest treatment or by a strict abstinence cure.
4. Ulcer of the stomach, recurring at shorter or longer intervals, notwithstanding a proper rest or abstinence cure.

Dyspepsia.

Hutchison, in the *Practitioner*, states that in acute catarrh of the stomach the principal thing is to give the inflamed organ rest. No food should be given when vomiting exists. Thirst is relieved by sips of hot water or by pieces of ice held in the mouth. Stimulation may be necessary if depression is present. Champagne is one of the best forms in which to administer it. Rectal feeding is resorted to only in cases of persistent vomiting. A return to the ordinary diet is made after the symptoms subside. In the chronic form of gastritis it is necessary to avoid irritation of the mucous membrane of the stomach either mechanically or chemically. All crude and coarse articles, therefore, must be forbidden, such as the stones or skins of fruits, whole meal bread or oatmeal and tough meats. Mustard, spices, pepper and condiments of all sorts fall under the head of chemical irritants and are, therefore, injurious, and so is alcohol, especially in its most concentrated forms. Sugar, especially cane sugar, is also harmful, as it is a potent excitant of mucous secretion. Most fatty substances, especially cooked fats, are injurious, but butter and bacon fat can usually be eaten in moderation. Care should be taken that the food is finely divided, eaten slowly, and but little consumed at a time. The following schedule would represent a diet suitable for an average case:

Breakfast.—Lightly cooked eggs, white fish (boiled), but not mackerel or herring, a little crisp bacon (not too fat), fowl or game, hard, dry toast, with a little butter (no marmalade), a small cup of tea, with milk but no sugar.

Luncheon.—Lean mutton, roast beef or white fish, etc., as at breakfast; a spoonful of mashed potato, with a little spinach or cauliflower; dry toast or a rusk or two; custard pudding or sweetened jelly, and a glass of alkaline mineral water.

Dinner.—A very little clear soup free from fat, white fish (boiled), without sauce; meat as at luncheon, or a little sweetbread; vegetables, as at luncheon; custard, jelly, or stewed fruit (free from skins and stones), or a little plain milk pudding; dry toast; no savory or dessert; a glass of mineral water; no coffee.

Pepsin.

Chase, in the *Boston Medical and Surgical Journal*, discusses the therapeutic value and the indications for the use of pepsin in diseases of the stomach. The important question is, In what disease of the stomach is pepsin indicated? In answer to this, the author states: "In all gastric affections, regardless of their cause, in which free HCl is present, pepsin is not indicated, because after proper acidulation of the gastric juice it becomes active, showing that pepsin is still present. These two classes of gastric disorders comprise over 90 per cent. of all stomach affections, and in their treatment pepsin is never indicated. In all cases of atrophic gastritis and achylia gastrica and in some cases of cancer of the stomach, both HCl and pepsin are lacking. As a result there is a true indigestion of certain foods in the stomach." Pepsin is active only in the presence of a certain amount of HCl. Chemical examination of the gastric juice is necessary in order to determine accurately any deficit of HCl. The theory has been accepted that HCl and pepsin given by mouth would take the place of those agents when they are lacking in gastric juice. In practice it has been found they do not. Of the use of pepsin the author quotes the following opinions:

Einhorn: "Pepsin used to be and is yet frequently given in combination with HCl. Most writers, however, concur in the absolute inefficacy of this drug, and for two reasons: 1. In the most instances, even of the diminished secretion, there is yet an abundant quantity of pepsin present. 2. Most pepsins in the market do not, by any means, show as strong digestive properties as the true pepsin of the stomach. Of late years I have entirely abandoned the use of pepsin."

Ewald: "Pepsin was for a long time regularly prescribed with HCl with the pernicious idea that if it did not help it certainly did no harm. Its use should be restricted to those cases in which an absence can be proven."

Riegel: "In general, the administration of pepsin is rarely indicated. The digestion of albumin is rarely improved by the administration of the hydrochloric acid, even if large doses are given together with pepsin. This is due to the fact that the quantity of HCl that we can administer is very much smaller than the quantity needed to make up the deficit of HCl in the gastric juice."

Chase believes that the best therapy is obtained by a stimulation of the function of the stomach rather than by a useless or even successful attempt at their substitution.

Medicolegal

Restriction on Sale of Cocain.—Chapter 203 of the Laws of Nebraska of 1905 provides that no apothecary, druggist or other person shall be permitted to sell or give away any quantity of cocain, except on the prescription of a physician, said prescription not to be refilled, provided that nothing in this act shall prohibit sale from manufacturers or wholesale dealers to retail druggists, physicians or dentists, nor the use and prescription of this drug by dentists in the practice of their profession. Every person offending against the provisions of this act shall be fined not less than $20 nor more than $100.

Physicians and Internal Revenue Special Tax.—"Can a physician, not having a revenue license, and furnishing his own medicines, prescribe alcohol or whisky for his patients, without violating the internal-revenue laws?" The answer of the United States Commissioner of Internal Revenue to this question is, as per ruling of Oct. 13, 1905: He can not prescribe and furnish to his patients alcohol or whisky, or any other alcoholic liquor not compounded into a medicine by admixture with drugs or medicinal substances, without involving himself in special-tax liability under the internal-revenue laws, even though he thus sells such liquor for use as medicine only.

Restrictions on Marriage.—Chapter 126 of the Laws of Indiana of 1905 provides that no license to marry shall be issued where either of the contracting parties is an imbecile, epileptic, of unsound mind or under guardianship as a person of unsound mind, nor to any male person who is or has been within five years an inmate of any county asylum or home for indigent persons, unless it satisfactorily appears that the cause of such condition has been removed and that such male applicant is able to support a family and likely to so continue, nor shall any license issue when either of the contracting parties is afflicted with a transmissible disease, or at the time of making application is under the influence of an intoxicating liquor or narcotic drug. If persons resident of the state, with intent to evade these provisions, go into another state and there have their marriage solemnized with the intent of afterward returning and residing in Indiana, and do so return and reside in Indiana, such marriage shall be void and such parties shall be subject to all the penalties provided for in this act.

State Laboratory of Hygiene—Adulteration Formulas.—Chapter 38 of the Laws of Indiana of 1905 provides for the establishment of a state laboratory of hygiene as a department of the state board of health. It shall be at Indianapolis and shall be used for making analyses of foods and drugs for the purpose of enforcing the pure-food and drug laws, for making sanitary analyses, pathologic examinations and studies in hygiene and preventive medicine, to aid in the enforcement of the health laws. All work done in it shall be done exclusively for the public benefit, and no fees shall be charged. For the conduct of the state laboratory of hygiene the state board of health shall appoint a superintendent other than the secretary of such board of health, and such superintendent shall have charge of and superintend and manage such laboratory. He shall be learned and skilled in bacteriology and pathology, and shall receive a salary of not to exceed $2,000 per annum. The state board of health shall also employ a skilled chemist, whose salary shall not exceed $1,500, and both appointees shall be temperate, healthy, well recommended and of good moral character. Another provision of this act is that any person who shall sell, offer for sale or give away, barter or trade any receipt or formula for the adulteration or imitation of food, or teach or offer to teach any method or means of adulterating any article of food or means of producing or manufacturing any imitation of any article of food within the state of Indiana shall be guilty of a misdemeanor, and on conviction thereof shall be fined any sum not exceeding $1,000, to which may be added imprisonment in the county jail not exceeding six months.

Registration of Vital Statistics.—Chapter 98 of the Laws of Nebraska of 1905 provides for a state registration of vital statistics. It provides that the undertaker or person in charge of the funeral of any person dying in the state shall cause a certificate of death to be filled out with all the particulars contained in the standard blank adopted by the United States Census Bureau, including a statement of the cause of death, made by a person holding a valid license as provided in Section 7, Article 1, Chapter 55, of the compiled statutes of the state for 1903, who was last in attendance on the deceased; or, in his absence or default, by the local health officer or coroner. Said certificate shall show clearly the course of disease or sequence of causes ending in death. A certificate of the standard form adopted by the United States Census Bureau shall be made out by the physician or other person attending the birth of every child born in the state, or, in default of such person, by the parent, etc., and filed with the local or subregistrar within three days from and after such birth. In case a child is born dead, both birth and death shall be reported, and the month of uterogestation shall be stated as nearly as possible by the attendant. The state registrar shall supply all necessary blanks, forms and instructions to the local registrars, and through them to physicians, etc. Any physician or other person violating the provisions of this act, or failing properly to register a birth or death as herein required, shall be deemed guilty of a misdemeanor, and on conviction thereof shall be fined not less than $10 nor more than $100, or be imprisoned for not more than 60 days, or be subject to both fine and imprisonment.

Dipsomaniacs and Persons Addicted to Narcotics.—Chapter 82 of the Laws of Nebraska of 1905 provides that dipsomaniacs, inebriates and persons addicted to the excessive use of morphin, cocain or other narcotic drugs shall be admitted, detained, cared for and treated in the Nebraska Hospital for the Insane. If, on investigation, the commissioners of insanity shall find the information filed to be true, they shall impose a sentence of detention in the hospital until the patient is cured, not exceeding three years. The patients shall be placed in a separate ward at the hospital, and shall be given such method of treatment as is deemed best to eliminate the effects of alcohol or narcotic drugs and to build up the system physically and mentally and which will tend to strengthen the moral character of the patient and enable him or her to resist the temptation to use alcoholic or narcotic drugs. Any patient whom the superintendent of the asylum believes to be cured may be paroled, conditioned on the patient's signing a written pledge agreeing to refrain from the use of all intoxicating liquors as a beverage and from the use of morphin, cocain and narcotic drugs during the term of his commitment and shall avoid frequenting places and the association with people tending to lead him to the use of the same. And such paroled patient must make written reports to the superintendent on the first day of each month, on blanks to be furnished for the purpose, to the effect that he has not during the past month, in any respect, violated any of the terms of his parole, which report must be investigated and approved by the clerk of the commissioners of insanity of the county in which the patient resides, who may demand from such patient satisfactory evidence as to the truth of his report. If, at any time, a patient on parole shall fail to make said report, or shall fail, in any respect, to fulfill all of the conditions on which said parole was granted, he may, without any further proceeding whatever, and on the written order of the superintendent of said hospital, be taken and returned to said hospital, there to be detained and treated as provided herein.

1.—See abstract in The Journal, Oct. 14, 1905, page 1190.

3. **Scheme for the Sanitary Control of the Municipal Milk Supply.**—Goler advises the establishment of a bureau of milk inspection, of which the chief sanitary officer is the head, and through whom licenses are issued for the vending of milk in the city. Boards of physicians and scientists appointed by medical societies should compile rules for the production and distribution of milk of higher nutritive value and lower bacterial content than ordinarily good city milk. Directly, or through the inspectors of the bureau of milk inspection, or through inspectors appointed by the commission itself, they should insure: (1) Character of stable and feed of cattle, health of milkers and care of utensils. (2) A negative tuberculin test. (3) A bacterial standard, not greater than 10,000 bacteria per cubic centimeter. (4) A nutritive value of 12.5 per cent. of solids, of which 4 per cent. must be fats. The necessity for the organization of the milk work for a municipality under one executive head having the license power can not be too strongly emphasized, for by this means only may the producer and the vendor be under sanitary control. When such laws are enacted for any municipality as will make it an offense punishable by fine or imprisonment to bring milk into the city that has not had the seal of sanitary approval set on it, and everything with which it comes in contact, our children and ourselves will no more be exposed to the dangers that arise from dirty, disease-bearing milk.

4. **Year's Work in Appendicitis.**—Traver reviews the cases of appendicitis under his care during the past year, and from a study of these concludes: (1) Chronic cases demand operation because an appendix once diseased does not return to its normal condition. (2) In acute cases, an early operation is demanded, as no physician or surgeon can tell how a case will terminate, and after pus is formed the golden time for an operation is already passed. (3) Cases complicated with general peritonitis give a high mortality under any treatment.

5. **Insomnia.**—Christison discusses the jerkings, shocks and hallucinations apt to occur in the initial stage of sleep; hallucinations of vision and hearing, the frequent prodrome of insanity; numbness, nightmare, convulsions, somnambulism and choreic jerkings which are apt to occur during sleep or on waking.

6. **Limitation of the Principle of Privileged Communications.**—According to Benedict, the adoption, as a rule of ethics, of the principle that all professional communications should be absolutely privileged goes further than the underlying principle of protection of weak and erring humanity, and may extend so far as to involve the physician as *particeps criminis*, in a social if not a legal sense. The underlying consideration on which professional secrecy is based is not that the physician belongs, body and soul, to every sick or injured man who appeals to him for assistance, but that the physician should be a negative quantity, so far as the social or legal punishment of sin or discredit is concerned. When a patient, after being warned and expostulated with, deliberately decides to transmit disease, to defraud a victim, to endanger lives, professional secrecy should no more be required of the physician than is the concealment of a case of quarantinable disease for the sake of the selfish interests of the patient.

7. **Local Anesthesia in Radical Cure of Inguinal Hernia.**—Bodine has operated on 284 patients, with 300 hernias, under local anesthesia, without a death or suppurating wound. By means of Schleich's infiltration method the amount of cocain is reduced to a minimum and limited to a small area, producing acute local anemia, effectually retaining the fluid in one spot. Cocainization of a sensory nerve trunk, abolishing pain sensation in the region supplied by it, renders it possible to operate for hernia by its use. The operative area is superficial, and the region restricted by the anatomy of the parts. In strangulated hernia, local anesthesia does not increase the shock, while general anesthesia is often too great a load to be borne. The local anesthetic permits of the application of hot towels to a possibly gangrenous intestine for some time, in order to determine whether it will react. The operation does not give rise to the danger of injury to the nerve fibers. The danger to a line of deep sutures from vomiting is done away with. There is no danger of cocain poisoning with the small dose necessary—that is, one-half grain injected intermittently throughout an hour. Morphin given after the operation would act as an antidote were poisoning possible. The operation is more thorough because of the absence of haste and the lack of need to save the patient pain. There are no evidences of pain during the operation. The cocain solution should be made fresh. The solution is 0.2 per cent. for infiltration of skin and nerve trunks, and for subdermic infiltration half this strength is used. The line of skin incision should be infiltrated throughout its extent sufficiently tightly to maintain the local anesthesia for an hour. The aponeurosis of the external oblique requires no infiltration. It should be incised over the situation of the underlying ring; the ilioinguinal nerve will be exposed by retracting the flaps, and its trunk is then cocainized by a few drops of the solution. The incision may be carried painlessly into the external ring, and the flaps reflected to expose Poupart's ligament and the conjoined tendon. The iliohypogastric, if found, may be cocainized. The margins of the internal ring are infiltrated. A line of infiltration along the long axis of hernial protrusion permits a clear cut through the hernial sac and coverings. The neck of the sac is infiltrated, dissected away from the underlying cord, ligated, and amputated. The genitocrural nerve is cocainized. The sac is dissected away from the cord, and the operation is completed. Operation on the female is easier than on the male, because the round ligament is less sensitive than the cord.

8. **Etiology of Tabes.**—Von Raitz attacks the view that tabes is caused by syphilis, and points out the injustice from social, legal and therapeutic standpoints that is caused to

patients by this assumption. He says that those who accept syphilis as the cause of tabes have no difficulty in finding syphilitic evidence in everybody who has tabes. If a patient admits having had syphilis, no further proof is necessary; if syphilis is denied, every disturbance at the genitals, no matter whether it be a specific or a simple urethritis, a vulvar abscess or abrasion, a chancroid or a simple sore, is sufficient evidence of syphilis. If disturbances at the genitals are denied, then any eruption on any part of the body furnishes the proof. And if everything is denied, then the "benefit of the doubt" is used to establish syphilis, and so the hundred per cent. is accounted for and tabes stands as a postsyphilitic disease. He then contrasts the pathology of syphilis and that of tabes, to show that the lesions of the nervous system in the two conditions have nothing in common, the degenerations of the latter disease being foreign to the former. It is also absurd to believe the syphilitic virus can remain dormant, and, furthermore, if tabes were a postsyphilitic disease antisyphilitic treatment would have a curative effect, but it has been found that the reverse is the case. Von Raitz believes that tabes is the result of various etiologic factors, prominent among which are sexual excess, toxins of various sorts, injury to the cord by falls, twists, etc., and the use of mercury.

9. **Eye Defects Associated with Puberty.**—Wheelock describes seven cases of defective vision occurring in boys and girls shortly before the age of puberty. They are characterized by great loss of vision, marked limitation of the visual field, and an eye ground varying from the normal to frayed blood vessels with a "shot silk" fundus, while the general health of the patient remains good. These phenomena he believes are due to change in the nerves and blood streams incidental to the development of the reproductive organs, as treatment is of little avail and recovery is not complete until menstruation has been established in girls and the seminal function in boys. Points Wheelock particularly emphasizes are: The existence of defective vision for distance and reading, limitation of the field for form and color, the age of the patients from 8 to 16 years, the absence of chlorosis or hysteria, the existence of a leucocytosis, and the recovery of normal sight both for reading and distance with much contracted field. The treatment involves restoration of hemoglobin and nerve force by iron, strychnin and manganese. The author suggests that there may be some connection between this condition and chorea.

10. **Diagnosis of Carcinoma of Stomach.**—McIntosh, in discussing the difficulties attending the early diagnosis of carcinoma of the stomach, in order to show the unreliability of symptoms, cites two cases in which complete recovery under non-surgical treatment followed in spite of the fact that several consultants had expressed the opinion that malignant disease was present. He says that the life of a gastric carcinoma may be divided into three periods: 1, From inception to the appearance of an exudate; 2, from the beginning of the exudate to the breaking down of the neoplasm; 3, from the breaking down of the neoplasm to death. Measures intended to enable the diagnosis to be made during the first period are impracticable, but the earlier in the second stage the nature of the disease is recognized the better are the patient's chances of cure. McIntosh describes the tests for detecting occult blood in the stools, and mentions such newer methods as Salomon's albumin test, Gluzinski's test, and the estimation of fatty acids in the urine. If HCl is absent, lactic acid is present, and there is inability to digest albuminous food, a diagnosis may be made even if no tumor can be felt. The diagnosis should be made from several examinations rather than from a single one, and this is especially true of chemical examinations of the stomach contents. For example, in stenosis of the pylorus due to a cicatrix from a former ulcer there may be the following symptoms: Cachexia, emaciation, ectasia, a decided tumor, and quite likely hematemesis. These are very suggestive of carcinoma, but the examination of the stomach contents reveals a large amount of free hydrochloric acid and no lactic acid. In this class of cases an examination should be made every week to ascertain if there is any change in the constituents of the stomach contents; the whole matter will hinge on this very point, and if there is no substantial change the diagnosis is pyloric stenosis, but of a benign nature. If there is progressive decrease in the HCl and development of lactic acid, with weakened albumin digestion, it is carcinoma. A reliable diagnosis can never be made from one symptom.

St. Louis Medical Review.

12 *The Cradle. J. Zahorsky, St. Louis.
13 *Retroperitoneal Teratoma. C. M. Nicholson, St. Louis.

12. **The Cradle.**—Zahorsky protests vigorously against the fashion of using no cradle for pacifying children. He considers the cradle a hundred times less objectionable than the modern devices which have been forced in place of it, such as the rubber pacifier, soothing syrups, etc. He urges that the cradle be returned to the nursery, especially in those homes where no nurse or nursery maid attends the baby. He considers the cradle one of the best therapeutic agents for a nervous baby or a sick one. It is easier on the mother and it is far preferable to the pacifier or paregoric. The irritability and peevishness in infants vary to such an extent that ordinary rules in regard to hygiene and management must often be very much modified. Here is where the cradle can be used to advantage. Zahorsky says that the signs of the times are that the cradle will again come into fashion; meanwhile the physician will do well to remember this well tried soothing agent for peevish children when ordinary means fail.

17 *Diagnosis of Cancer and Ulcer of the Stomach by the Use of Expert Methods of Clinical Procedure. H. F. Hewes, Boston.

17. **Laboratory Diagnosis of Gastric Ulcer.**—Hewes examined 160 cases of stomach disorder by the methods outlined by him in a previous paper. Of this number anatomic or pathologic diagnosis was obtained in 37. In these 37 cases the corresponding records of the clinical diagnosis made previous to operation and of the anatomic diagnosis or pathologic made at operation or postmortem were as follows: In 18 cases clinical and pathologic diagnoses of cancer were made in all. In 12 cases diagnosed clinically as ulcer, the pathologic diagnosis was ulcer in 11 cases and cancer in 1 case. In 1 case a clinical diagnosis was made of gastrectasis, probable cause cancer or ulcer; a pathologic diagnosis was made of adhesions about the pylorus from the gall bladder. In 1 case the cause of the symptoms was unknown; the stomach contents were normal. The pathologic findings were chronic appendicitis with enlarged mesenteric glands; the stomach was normal. In 3 cases a clinical diagnosis of neurosis was made, there seemed no cause for operation. Pathologically no lesion of the stomach was found. One patient with hypoacidity was operated on for ventral hernia and explored for possible cancer; the stomach contents were normal except for hypoacidity; pathologically the stomach was found intact. That is, in 31 cases of stomach disorder in which the clinical findings pointed to the existence of cancer or ulcer of the stomach and in which such a diagnosis was definitely made from the findings, one of the two lesions was found present in all, and the diagnosis of the type of lesion was correct in all but 1 case; in 3 cases in which no cause for operation was found by clinical findings, no cause was present on operation; in 2 patients in whom the clinical findings failed to show definitely evidences of an organic lesion, but who were operated on for other reasons, no lesions of the stomach were found. Hewes says that the accuracy of the indications gained by these clinical methods of examination is still more marked if we study the testimony of the records in regard to the diagnosis of the location of the diseased conditions. These records show: In 9 cases there was a clinical diagnosis of cancer at the pylorus. The pathologic finding in these 9 cases was cancer at the pylorus in all. In 9 cases a clinical diagnosis of ulcer involving or occluding the pylorus was made; the

pathologic diagnosis in these cases was ulcer at the pylorus in 8 cases, and of cancer at the pylorus in 1 case.

25 *A Protective X-Ray Tube. L. M. Liebermann, New York.

20. Expulsion Method of Obtaining Stomach Contents.—Turck believes that he has overcome the difficulties ordinarily encountered in attempting to gain the stomach contents, by the adoption of the so-called expulsion method which he has used for many years and has found to be of great practical value. A double stomach tube of special design is introduced, and by means of compressed air introduced through one compartment of the double tube the stomach is inflated and the contents are forced out through the other compartment of the tube, which is the larger, and extends deeper into the stomach. By a careful and judicious manipulation of the tube the entire stomach contents can be obtained. The aspirating bottle, designed by Turck, has the advantage of being a graduated receptacle which is ready for transportation to the laboratory. It consists of a wide-mouthed bottle, holding 300 c.c., graduated, closed with a rubber stopper with two openings, through which bent glass tubes are passed, one tube attached to an aspirating bulb and the other connected with the stomach tube. Turck employs a double tube, one small caliber tube for the inflow attached parallel to a large size tube for the outflow. This arrangement more readily conforms to the shape of the esophageal opening, which is oval, flattened in the antero-posterior diameter. The end of the smaller inlet tube reaches to the upper portion of the stomach just beyond the cardiac orifice, and is perforated with small needle-like openings or a single large opening, while the larger or outlet tube extends to the greater curvature or floor of the stomach, with large end and side openings to allow free flow of the stomach contents. When the tube is inserted into the stomach the small caliber tube is connected with a large hand compressing air bulb and air is pumped into the stomach. The tube is introduced into the patient's stomach in the usual way, requiring less difficulty rapidly to reach the stomach owing to a small wedge of solid rubber where the two tubes are united parallel to each other, which prevents kinking and delays in introducing the tube. This is very essential in nervous patients for obvious reasons. The tube being connected with the air apparatus, the air is allowed to enter the stomach, distending it. The rugæ are stretched out and a smooth surface results, and at the same time the stomach, on inflation, rotates anteriorly and upward, thus bringing the contents in contact with the end of the stomach tube, when, the air being allowed to escape, the stomach contents are carried with it into a convenient receptacle. A practical receptacle for office treatment is a bottle with a rubber stopper perforated by two holes, through which pass glass tubes. One tube is connected with the stomach tube and the other is left open to allow the escape of air from the bottle. The method can be carried out in from ten to thirty seconds. Some of the advantages enumerated by Turck are the following: The folds of the stomach mucosa are prevented from occluding the openings of the outlet tube. The air expels the contents in any desired amount, with great facility and with little distress for the patient. There is little danger of injuring the mucous membrane. It is impossible to overdistend the stomach, which can be emptied thoroughly, and the method does not prevent the use of the expression or the aspiration method in combination. The degree of force with which the air returns furnishes data of the character or tone of the muscles. The amount of air introduced under a given pressure gives an idea of capacity. By connecting with a manometer, the degree of pressure can be ascertained and the tone of the stomach wall estimated. Diagnosis between stenosis of the pylorus and atony of the stomach wall is facilitated. Patulous cardia and pylorus can be diagnosticated. When the stomach is dilated and filled with food and liquid, exciting peristalsis by introducing air and allowing it to escape again, after a brief period of waiting, may cause the stomach to empty itself, showing that retention is due to atony and not to stenosis of the pylorus. The introduction of nebulized oil, and the degree of force with which it escapes, gives valuable data of the character of the muscle walls and at the same time applies mild disinfection and stimulation to the gastric mucosa. This method combines the advantage of promptly securing the stomach contents and of inflating the stomach for outlining the organ by percussion.

22. New Rectal Valvotomy.—Hirschman has devised a simple technic which has proved most satisfactory in his hands. The patient is put in the knee-shoulder position, and a large operating size proctoscope is inserted after the sphincter has been prepared for it, either by gradual dilatation or by immediate divulsion following local anesthesia of the part. The ligature carrier devised by Hirschman is threaded through the eye at the curve with a rubber ligature (size 5 to 8, French scale); the ligature passes inside of the curve of the needle and should project about half an inch from the point. The needle, which is nine inches long and has a handle bent at an angle so as not to obstruct the view, is then passed up around and hooked through the highest offending valve until the point is projected and the ligature can be clearly seen. This end is then grasped by means of a long forceps and the ligature is pulled through until it is outside the proctoscope. The needle is then passed back and around the edge of the valve and is brought down also outside the proctoscope, and is then taken off the ligature. The ligature is now in place. Over the ends is slipped a lead fastener or large perforated shot, the ligature being put on the extreme stretch, the shot is grasped and pushed up to the valve tightly by means of long compression forceps and is firmly compressed. This puckers the valve and constricts it in such a way that circulation is shut off and the ligature sloughs through in from two to eight days. After the ligature has cut through, the edges retract so that a large V-shaped opening is left, which gradually retracts still further. The advantages of the method are said to be, the fact that it can be done without any anesthesia whatever; it can be done quickly, the whole operation not requiring more than ten minutes for three valves; it requires few instruments or appliances; the patient is not confined to bed; there is absolutely no hemorrhage; no stitches are required; the rubber ligature, being soft and non-irritating, does not scratch or bruise the bowel *in situ* or during its expulsion, and there is no danger of its doing damage if it should by any possibility be carried up higher into the bowel.

25. Protective X-Ray Tube.—The device employed by Liebermann consists of a form of tube in which the anode disc is placed within the tubular neck, or extension, which latter is covered with a lead flux glass cylinder of sufficient thickness to prevent all leakage of ionizing rays, and in which is provided an opening for the passage of such rays. In connection with this ingeniously contrived tube a set of lead glass specula —of two sizes—serve to localize completely the volume of escaping *x*-rays, and thus render the interposition of lead foil protective entirely unnecessary. This lead glass speculum serves as a collector and director of the ionizing rays excited within the tube, acting at the same time as a tubular diaphragm.

30 *Bacterial Treatment of Sewage and Its Adaptability to Small Communities. R. F. Palmer, Roosevelt, Arizona.
31 *Study of the Results of Abdominal Hysterectomy for Fibroids of the Uterus, with and without Drainage. J. Brettauer, New York.

26. **Pericardial Effusions.**—Jones discusses the clinical history of this affection and emphasizes the importance, as a diagnostic aid, of eliciting flatness on percussion in the fifth interspace to the right of the sternum. He cautions against confusing a flat note on percussion with the dull note. In all cases of suspected pericarditis the physician should watch carefully with reference to the developing effusions.

27. **Antitoxin for Mushroom Poisoning.**—Ford has prepared an antitoxin from the various varieties of poisonous mushrooms. His method is as follows: The fungi are dried in the sun and an extract made later by macerating them in water, expressing them between folds of linen cloth, filtering through ordinary filter paper, then through a Berkefeld filter under pressure. As thus prepared the extract is a thin, dark brown fluid which may be kept almost indefinitely without losing its toxic properties. The toxic principle contained in this extract, known since Kobert's time as phallin, is strongly hemolytic. When brought to isotonic solution by the addition of requisite amounts of NaCl it quickly dissolves the erythrocytes of man, cattle, swine, sheep, goats, rabbits, dogs, guinea-pigs, hens and pigeons. Heated to 65 C. it loses this property completely, and the capacity of dissolving the corpuscles is not restored by the addition of serum, lecithin, cholesterin, milk, or any other substance which has thus far been tried. The hemolytic principle thus belongs to the category of bacterial hemolysins, and not to the serum hemolysins. This extract is very poisonous to small animals. Following the injection of fatal quantites subcutaneously, in both rabbits and guinea-pigs, there is an extensive subcutaneous edema with hemorrhages in the lymphatic glands, in the serous membrane, and in the internal organs, especially the liver and kidney. The heart always stops in diastole, and the blood may be fluid if the dose has been large. Death occurs usually within four or five days, although it may occur after the lapse of two or three weeks, owing probably to degenerative changes in the liver and kidney. If rabbits be treated with repeated small doses of phallin subcutaneously, followed by large doses intraperitoneally, it is possible to immunize them against the action of multiple toxic doses. The mortality among animals so treated is very great, but successful results have been thus far obtained with five or six rabbits. These animals were eventually able to withstand the injection of about five times a fatal dose and their blood serum exhibited definite antihemolytic and antitoxic properties. The strongest serum thus obtained will neutralize the hemolytic principle of phallin in a dilution of 1 to 10,000, using as an index of hemolysis the quantity of phallin just sufficient to dissolve 1 c.c. of a 5 per cent. solution of rabbit's blood. The same serum possesses antitoxic properties in a dilution of 1 to 10, 0.5 c.c. completely neutralizing five times the fatal dose for rabbits.

30. **Disposition of Sewage in Small Communities.**—Palmer describes the syestem of sewage in operation at the geological survey camp at Roosevelt, Ariz. It consists of a septic tank, followed by a continuous trickling filter. Approximately 3,000 gallons of sewage pass through the tank and filter in twenty-four hours. The tank is of concrete floor and sides with a board roof covered with earth. It is 40 feet long, 8 feet wide and 3 feet deep, and divided into three compartments by two walls. It has a capacity of about 3,600 gallons, so that the sewage remains in the tank between twenty-four and thirty hours. The inlet to the first compartment is by a six-inch pipe, connected with the main sewer, one foot below the surface of the fluid when the tank is full. This compartment is the grit chamber and measures 5x8 feet and is 6 feet in depth. From here the sewage passes through an opening in the dividing wall one foot beneath the surface into the septic chamber 8x30 feet and 3 feet deep. In this compartment are a number of partitions extending alternately from either side of the tank and extending nearly across. These partitions retard the flow of sewage and permit of greater fermentation. The sewage now passes through another opening one foot from the surface into a small compartment, from which the effluent overflows at the top into a four-inch iron pipe, and is conducted by it to the distributor. The distributor consists of a box 4 inches square and 3 feet long, with eight cross sticks passing through. These cross sticks are grooved on top, and, as the effluent rises in the box to the level of the grooves, it passes out and flows over the sides of the cross sticks and drips on the surface of the filter. The filter is a wood frame 1 yard square and 10 feet high, placed on a slanting concrete floor. The sides of the frame are latticed so as to give plenty of air. The filling material is of small boulders between two and three inches in diameter. On the floor is a collecting drain which leads by a short outflow pipe to the power canal.

31. **Drainage in Abdominal Hysterectomy for Fibroids.**—The study of the value of drainage in abdominal hysterectomy for uterine fibroids was undertaken by Brettauer with a view to ascertaining the difference in the immediate results of abdominal hysterectomy on the comfort, rapidity of convalescence, and general condition of the patient, in those cases in which drainage through the vagina was instituted, and in those in which it was omitted. Of the 54 operations discussed, 32 were performed with gauze drainage through the cervix and 22 without. Brettauer found that there is not the slightest difference in the immediate postoperative course whether drainage is practiced or not, although he considers it preferable to sew up the abdomen in all cases so as to assure a more perfect hemostasis.

37. **Simple Technic in Herniotomy.**—Witherbee advises leaving the cord alone and sparing the tissues all unnecessary manipulation. He says that it is also unfortunate that in transplanting the cord, it should be allowed to monopolize so large a surface of Poupart's ligament. The latter can be turned to a far better purpose by bringing in contact with it as large an area as possible of the internal oblique. The operator should endeavor in all ways to effect the strongest union between it and the structures opposite. Due precaution should be taken that the sutures do not interrupt the blood supply, else sloughing will occur at the expense of approximation. To overcome this Witherbee uses exclusively the figure-of-eight suture, which, he says, if properly inserted, can not be adjusted with sufficient tension to stop the circulation. It has the additional advantage of being removable, and consequently does not overburden the power of absorption. To insure fixation and at the same time to relieve the skin from undue pressure, a U-shaped plate is employed, to the arms of which are attached the sutures after they emerge from the skin. Four silkworm-gut sutures thus introduced will effectually approximate both layers of Poupart's ligament with the ex-

ternal and internal oblique, the transversalis and rectus, if necessary, and will maintain their approximation for an indefinite period, or until firm union has unquestionably taken place.

49. **Quinin in Pneumonia.**—Ramsey details his experience with quinin in the treatment of lobar pneumonia. When first called to a case of pneumonia, he orders a warm bath, gives a mild cathartic, and, if the pain is at all distressing, he gives a hypodermic of morphin. If the pain returns it can usually be controlled by applying the ice bag. He has discontinued the use of all external applications, as he has not found them satisfactory. He then orders the administration of 30 grains of quinin, repeated in one hour, and again, in some cases, in two hours, depending on the amount of fever and condition of the patient. With the third dose he gives some form of iron, usually reduced iron, in doses of from 3 to 5 grains, repeated every three or four hours. When nervousness is marked, bromids are given, frequently combined with chloral in 10-grain doses. When the rusty sputum is profuse he gives capsules containing 1 grain of acetate of lead, three or four times a day, for two or three days, and while administering the lead he discontinues the iron. He believes that quinin is the most reliable stimulant we have in this disease.

56. **Difficulties in Abdominal Diagnosis.**—Francis discusses this question, and as an illustration cites two cases, one which was diagnosed as a case of intestinal adhesions, when there were none, and the other having been diagnosed wrongly a number of times, operation disclosing it to be a case of intestinal adhesions. He concludes that the diagnosis of abdominal conditions depends very largely on the skill and training of the examiner as well as on the physical and other characteristics of the patient. The examination should be systematic and thorough. Inspection, palpation and percussion, with the patient both supine and erect, are the best means of diagnosis. Bimanual examination and particularly examination of the pelvis should never be omitted. A general anesthetic is sometimes, though rarely, needed. It is very important that not only the entire abdomen, but the entire body, should be examined so that the condition of every organ can be noted. Exploratory laparotomy is often warranted in doubtful cases and the decision when to employ it is one of the nicest points in modern surgery.

3. **Cause of Angina Pectoris.**—For many years Mackenzie has noted carefully the individual symptoms present in case of angina pectoris in order to find some cause for these symptoms, as well as the mechanism by which they are produced. In view of the fact that angina pectoris occurs in lesions of great diversity, Mackenzie believes that some condition common to all must be the cause of the symptoms. The fact that angina pectoris appears only after the heart muscle has been long exposed to excessive strain points to the cause being situated in the muscle. All the functions of the muscle fibers save that of contractility can be shown to be intact in many patients who suffer from angina pectoris. The alternating action of the heart is a demonstrable sign of exhausted contractility, and its presence is always associated with symptoms that are included in the symptom-complex of angina pectoris. The same exciting cause—extra strain on the heart—may provoke both the angina pectoris and the alternating action and both may disappear with the removal of the cause. The inference to be drawn from the consideration of these facts is that the symptoms that are included in the term "angina pectoris" are so closely associated with an impairment of the function of contractility of the muscle fibers of the heart that in all probability angina pectoris will be found to be an evidence of the impairment of the function of contractility.

4. **Syncopal Bradycardia.**—The chief point of interest in Maynard's case appears to be the undoubted evidence afforded of an independent action of the two sides of the heart. The descending or diastolic position of the sphygmograph curve showed no evidence of subsidiary pulsations communicated by the heart, and yet the ear and the hand detected secondary impulses which could not have failed to have been registered by the sphygmograph had these originated in the left heart. Hence Maynard concluded that the sounds and impulses referred to were produced in the right side of the heart during the diastolic pause of the left ventricle. The patient was treated with various drugs, including strychnin, with and without strophanthus, and mercury perchlorid; strychnin, on the whole, appeared to be most beneficial. The accelerated influence on the heart's action of either stimulants or exertion was very slight.

5. *Albuminuria of Adolescents.*—The form of albuminuria considered by Dukes is that usually referred to as early, latent, functional, cyclic, and intermittent albuminuria and which occurs usually among boys and girls at school. Dukes says that boys exhibiting the signs of the malady are sometimes sent from school on the ground that they are unsuited for the rough and tumble of school life. They are also excluded from all public appointments in the navy, army, and civil service at home and abroad. Life insurance is deferred or refused to these applicants, except at prohibitive rates. Dukes found that the larger class of patients exhibiting this symptom also exhibit increased arterial tension in consequence of irritability of the vasomotor nerves. This tension is very unstable and is most frequently produced by excess of nitrogenous food, by imperfect elimination, and by hereditary tendency to gout. A dose of blue pill and alkalids works wonders. The next most extensive class comprises those who have deficient vasomotor control. The treatment of this class resolves itself into abundance of food and tonics. The remainder are the spare, highly strung, oversensitive neurotics. The *bromids, judiciously administered* with occasional doses of blue pill, afford alleviation to patients of this type, but the only efficient remedy is the *removal of anxiety so that intellectual* work *may be* undisturbed by the intrusion of depressing feeling. Dukes says that when the albuminuria of adolescents is recognized and treated there is little likelihood of its proving the precursor of organic disease of the kidneys, even when its duration has been many years.

8½. **Operative Treatment of Congenital Cleft Palate.**—Results obtained in 67 cases of operation for congenital cleft palate are carefully tabulated by Berry. He never operates during the first 22 months of life, believing that some time during the third year of life, in the vast majority of cases, is the time when the operation can be done with most advantage to the patient. In some few cases of delicate children and ill-nourished children in whom the soft tissues covering the palate bones are thin, it may be advisable to postpone the operation to a somewhat later date, but the cases in which operation should be done after 4 years of age are extremely rare, says Berry. He has never declined to operate in any case under the age of 20, nor has he ever advised treatment by mechanical apparatus rather than by operation in any patient under that age. The operation performed by Berry has been on the lines of that originally introduced by Langenbeck and Ferguson. Briefly the operation consists of dissecting up a broad band of soft tissues from the hard palate on either side of the cleft, in detaching the soft palate completely from the posterior margins of the horizontal plates of the palate bones, and then, after these soft tissues have thus been brought down, in sliding them toward the middle line. Their inner edges are then united by sutures, either before or after lateral incisions have been made through the anterior part of the soft palate and posterior part of the mucoperiosteum of the hard palate. By these means even the widest cleft in the hard palate can be closed, although more than one operation may be necessary. Two points are essential for success. One is that the soft palate shall be completely detached from the posterior edges of the palate bones. If this is not done (even in most cases of cleft limited to the soft palate) the soft tissues in bad cases can not be brought down enough to enable the edges to meet in the middle line. The other point which demands consideration is the position and extent of the lateral incisions that must be made to relieve tension and temporarily to paralyze part of the soft palate. In ordinary cases in which the cleft is not very wide these incisions should be made after the palate has been sewn up. In cases of very wide cleft they must be made before the edges can be approximated. In his earlier operations Berry used to make these incisions too near the middle line from fear of wounding the posterior palatine artery, and too far forward from fear of encroaching too much on the soft palate, and thus endangering the vitality of the flap. He pays very little attention to the palatine artery. He cuts close to the teeth, and often right across the artery near its exit from the palatine foramen. The lateral incision should extend as far backward as the middle of the soft palate at its junction with the lateral wall of the pharynx.

18. **Ethyl Chlorid as a General Anesthetic.**—McCardie believes that ethyl chlorid occupies a position as an anesthetic about midway between nitrous oxid and ether. It is, as one would expect from its composition, more toxic than the former, and when used in properly selected cases nearly as safe as the latter. Nitrous oxid as regards safety is still in a class by itself. We should use ethyl chlorid rather to replace chloroform and ether in certain cases than to administer it as a substitute for nitrous oxid. For short operations needing longer and deeper anesthesia and greater muscular relaxation than nitrous oxid or nitrous oxid mixed with oxygen affords, ethyl chlorid is of great advantage. As a preliminary to etherization this anesthetic is unequaled. The contraindications to ethyl chlorid are connected with the upper air passages and particularly with inflammation or narrowing in or about the larynx—e. g., swelling or edema thereabouts. Patients suffering from goiter take it well unless there be marked dyspnea or stridor. McCardie is convinced that ethyl chlorid also is very useful in military surgery, owing to its portability and rapidity of action. In certain procedures, such as tying blood vessels and small amputations, it is necessary to operate on the spot before the patient can be safely transported to a base hospital. The saving of five or six minutes in the induction and of ten minutes in the recovery from narcosis in such conditions is most important, especially as the number of surgeons is always out of proportion to the number needed in a serious engagement. Time, too, could be saved by administering ethyl chlorid before chloroform. Again, in soldiers enfeebled by campaigning and suffering from great loss of blood, shock would be far less intensified by ethyl chlorid than by chloroform. After ethyl chlorid narcosis, patients are at once safely transportable.

19. **Motor Aphasia Without Agraphia.**—The great point of interest in Branwell's case is the fact that there was complete motor aphasia without any agraphia; any defect in writing which was present in the early stages of the case was clearly a mere defect of manipulation, a defect due to inability to hold the pencil and not an aphasic defect properly so-called. The aphasia was purely motor. Branwell is convinced that a sudden organic brain lesion, probably either embolism or hemorrhage, was the cause of the symptom.

20. **Thymus Gland in Children.**—Brickdale summarizes his article as follows: 1. The usual weight of a microscopically normal thymus in a child under 1 year is under 100 grains. 2. Children suffering from "primary atrophy" or marasmus commonly, but not always, exhibit fibrotic changes in the thymus; the weight and size of the organ are also usually diminished. 3. Children suffering from "secondary atrophy" exhibit similar changes, but they are not so constant. 4. Possibly some other factor than mere malnutrition or starvation may produce these fibrotic changes, as a case in which pure starvation was produced by congenital stenosis in the alimentary tract they were not observed. 5. In cases of acute illness in children, fibrosis of the thymus may accompany general wasting. It is difficult in these cases to exclude previous disturbances of nutrition, at any rate among hospital patients. 6. Enlargement of the thymus and other lymphatic structures in the body may occur as the result of acute toxic absorption (as in diphtheria) or a more chronic condition (as in lymphatism). In these enlarged thymus glands eosinophile cells are numerous, but no special types are peculiar to either class. 7. In some conditions, especially in tuberculosis, cells with basophile or neutrophile granules seem to replace the eosinophiles. 8. In congenital heart disease eosinophiles are not found in the thymus. 9. True hyaline degeneration very occasionally occurs in Hassal's corpuscles. 10. Fatty degeneration of the cells is common and appears often to affect the peripheral zone of the lobules.

29. **Enlarged Spleen in Pediatrics.**—Carrière discusses the various conditions liable to entail enlargement of the spleen in infants and differentiates a case under observation as splenomegaly with pseudoleukemic anemia in a rachitic child, aged 20 months. The possibility of a syphilitic origin for the condition imposes the necessity for specific treatment supplemented by nourishing food and tonics.

30. **Hysteric Fever.**—Caramano has had occasion to observe several cases of hysteric fever. He mentions that it is characterized by its sudden onset, without headache or chill, by its periodicity, and by the good general condition afterward, the patient being ready to eat at once. It usually comes on about 5 or 6 p. m. and subsides three or four hours later. The thermometer may go up very high and the pulse may become accelerated. He has noticed a pulse rate of from 130 to 140, with a temperature of from 39.5 to 41 C. (103 to 105.8 F.) The hysteric nature of the fever can be determined only after exclusion of all other causes. It sometimes follows a cold or sore throat, but is generally the result of autosuggestion. Hanot's patient was convinced she would have typhoid fever because she had attended two cases of typhoid, and Vaillart's thought she would have malarial fever because she had been visiting in Corsica. Treatment of hysteric fever should not be with drugs. Suggestion alone will conquer it. In 2 cases Caramano followed Widal's advice and gave his patients what he told them was a very active medicine and that it would be dangerous for them to take more than the two tablespoonfuls he ordered. If the drug acted properly the urine would turn

blue. The medicine was only a weak solution of methylene blue, with a few drops of nux vomica to give it a taste. Both patients were permanently cured in less than two days.

34. **Passage of Spirochetes into Serum of Blisters.**—Levaditi and Petresco relate a number of experiments and experiences which demonstrated that the *Spirochæta pallida* passed into the blisters made artificially on secondary syphilitic lesions on the skin, and also into blisters produced on sound skin in the vicinity of secondary syphilitic cutaneous lesions. Control experiments on non-syphilitic subjects invariably resulted negatively. The spirochetes were found in the blister over a secondary syphilitic lesion even when the skin was intact, but the findings were negative when the lesions were those of recent infection or were tertiary manifestations. The discovery of the spirochetes in an artificial blister may have important diagnostic significance in puzzling cases of syphilis.

38. **Organ Treatment of Nephritis.**—The Journal has chronicled Renaut's successful treatment of nephritis with a maceration of pig's kidneys. The technic was described on page 341 of volume xlii, 1904. Chaupin here relates in full detail his latest experiences with it in selected cases. The dose recommended for adults is *two kidneys a day for ten* days out of fifteen. The kidneys should be from young pigs and should not weigh more than 160 gm., selecting the lighter colored ones. The maceration has a very energetic diuretic action and also an unmistakable antitoxic property. The latter is demonstrated by the rapid subsidence of the symptoms, suggesting a general disintoxication, the edema and congestions vanishing, the arterial hypertension subsiding, and the enlarged heart becoming smaller. *In some cases this effect* occurs promptly, in others not for a long time. In one case this treatment was kept up for eleven months without improvement, after which amazing benefit was realized. The maceration *sometimes* has a laxative effect or may cause sweating. The albuminuria usually subsides, and sometimes there is increased excretion of urea and chlorids, with a higher "coefficient of oxidation." The general health invariably showed marked improvement. Other writers have reported 23 cases of severe nephritis benefited likewise by this organ therapy. Renaut does not regard it as a specific, but merely as an extremely valuable adjuvant to the usual measures.

51. **Tardy Traumatic Apoplexy.**—Marie and Crouzon describe a case of apoplexy with hemiplegia and aphasia developing in a man of 50, six days after he had been thrown from the top of a cab. Discussing this and similar cases on record, they conclude that *tardy traumatic apoplexy is due to* some lesion of the brain, generally hemorrhagic, produced by the accident in a predisposed subject. The influence of the predisposition, of arteriosclerosis in particular, can be readily traced in the traumatic cerebral processes, even when they assume the form of a neurosis. Whatever the predisposition, the rôle of the traumatism is no less capital. The physician confronted with these *tardy traumatic nervous affections* should seek for an organic cause and should study whether the traumatism alone is responsible or whether there may not be some underlying predisposition.

54. **Lack of Sufficient Nourishment in Dyspeptic and Nervous Persons.**—Mathieu and Roux *emphasize the fact that the* relative inanition in cases of dyspepsia and neurasthenia is liable to entail serious consequences, aggravating the primary ill and leading to others. The most important points for the diagnosis are *the behavior of the liver, tongue and stomach,* the perversion of hunger, and the mental condition. Loss of weight is an indication of relative inanition. The loss of fat *in the abdomen is liable to cause the liver to slide down and forward, and it may become reduced in size to 4, 5 or 6 cm.* When such a small liver is encountered, in the absence of cirrhosis, it is a sign that the patient has been inadequately nourished for a long time, and this assumption is corroborated by *the increase in the size of the liver when the patients are* better fed. The liver diminishes in size from loss of fat and of glycogen and possibly also from the lesser volume of the blood in circulation. Whether the lesser size of the liver is *actual or is merely an apparent reduction from the falling* forward of the liver, the symptom is very important for the diagnosis of relative inanition and allows its degree to be determined. The vanishing or perversion of the sense of hunger is another important sign. The perversion of hunger in nervous young women is sometimes shown by a feeling of nausea in the morning before arising and again about 4 or 5 in the afternoon. If they eat a little, the tendency to nausea vanishes. If this perversion of the sense of hunger is supposed to be the result of dyspepsia, and the food is still further reduced, the patients grow still weaker; plenty of nourishing food is *the natural remedy, and it should be insisted on with* decision and perseverance. This hunger with nausea resembles what Benda has called "hunger with fainting." His patients experienced at certain hours a feeling of faintness with great depression and sometimes nausea, cyanosis and cold sweats. Hunger with periodically recurring conditions of anguish is another variety. In these nervous conditions the appetite is satisfied with a few mouthfuls, and if more is eaten there is uncomfortable satiety. *This is especially liable to occur in* hysteric young women, and it requires great powers of persuasion and perseverance to overcome their resistance to take more food *when they feel satiated with the first mouthful.* The tongue of persons debilitated from relative inanition is generally white and dirty and there is splashing in the stomach. The digestive apparatus loses its fat and shrinks in size and the muscularis of the stomach becomes thin. The organ stretches with the smallest amount of food ingested, and five or six hours elapse before even a small meal is passed along out of the stomach. A splashing sound can easily be elicited in *the morning, fasting, after drinking 50 or 100 gm. of water.* Succussion will also reveal a floating sound near the umbilicus or even several centimeters below. The extreme dilatation of the stomach is apt to alarm the physician and to cause *him* to reduce the nourishment still more, but this is a grave error which merely aggravates and perpetuates the morbid condition.

Nourishing feeding will restore conditions to normal if persevered in, if the patient stays in bed or lies down most of the time. In the course of three or four months the stomach will be found to have returned to its normal dimensions. In one instructive case cited the patient gained 35 pounds and all disturbances ceased after institution of a suitable nourishing diet. This relative inanition is liable to entail simple neurasthenia, hysteria or fixed ideas. The prognosis is most favorable in the neurasthenic cases. The patients must be encouraged that all will soon come out all right, but that for two or three weeks after resuming abundant nourishment they are liable to have a number of more or less violent digestive disturbances. Such patients usually co-operate with the physician, but this is seldom the case in hysteric perversion of the appetite. Hysterical individuals are incapable of making an effort. The anorexia becomes a fixed idea, and psychic measures are necessary. The prognosis is much more unfavorable in the cases of hereditary degeneration with fixed ideas and phobias.

55. **Thiosinamin Test of Remains of Albumin in Feces.**—Rosenberg has been testing Oefele's thiosinamin test, but has found it unreliable. Thiosinamin, he says, dissolves coagulated egg albumin, but not the albumin in muscle and connective tissue.

56. **Chronic Spasm of Colon.**—Schütz reports 3 cases of chronic spasm of the colon. The patients were young women, two of them virgins. The assumption of appendicitis in one case led to an unnecessary operation. The contraction of the colon could be readily palpated, but it was dubious whether this was an idiopathic, purely nervous affection or the result of some lesion elsewhere. The spastic colon was movable and thinner than usual. The attacks were treated like lead colic. Purgatives merely added to the disturbances, and even oil enemata aggravated the condition. Opium and a liquid diet were the only means that brought relief. After the attack had commenced to subside, the tendency to contraction was combated with rest, hot applications, warm prolonged baths, belladonna, arsenic and regulation of the diet. All irritating foods, coarse bread and vegetables, had to be avoided. Massage is contraindicated, but slight vibration massage proved so beneficial in some cases that it should always be given a trial. Galvanization also demonstrated a favorable influence on the contraction. In one case the trouble was evidently a primary neurosis. In another there were symptoms of irritation in various nerve regions. The trouble is evidently the result of abnormal irritability of the nerves of the intestine in persons with a tendency to anemia and neuropathy. In two cases the trouble dated from the fourteenth and seventeenth year. In the first the attacks lasted from eight to twelve weeks and at last for six months, but they occurred only four times in five years. In the other patient they occurred frequently, but lasted only a few days, frequently coming on with the menses. Constipation was the rule among the patients. The pains are like cramps in the sides and across the abdomen, at first occurring only at stool, but gradually increasing in duration, with agonizing exacerbations. The bowels do not move at all, and there may be loss of appetite with nausea and broken sleep. The normal temperature, pulse and respiration exclude the idea of peritonitis. There is no sensitive region to be found in the abdomen outside of the contracted colon.

58. **Milk Diet in Tropical Diarrhea.**—Vogelius advocates an abundant and strict milk diet as offering the best chances for recovery in cases of tropical diarrhea. In a case described at length he commenced with 2.5 liters in twenty-four hours, gradually increasing to 3 or 4 liters and keeping up this exclusive milk diet for four or five weeks after the stools had become formed.

59. **Palpation of Sigmoid Flexure.**—Schilling gives minute directions for palpating the region of the flexure to obtain the maximum of information. He also cites a number of cases showing the results of this careful investigation, which afforded information of the greatest moment for the treatment.

62. **Congenital Myxedema.**—Argutinsky gives illustrations of a child with thyreoaplasia inducing congenital myxedema, showing the great benefit derived from fifteen months' thyroid treatment. He calls attention to the remarkable lowness of the umbilicus in the child before treatment and the gradual rise of the umbilicus to its normal position as treatment progressed. He has found a dozen other cases illustrated in the literature, the pictures showing the umbilicus remarkably low on the abdomen. When thyroid treatment is not instituted, the children grow up with this anomaly, but in the illustrations of children thriving under thyroid treatment the umbilicus seems to have risen to its normal location.

65. **Spontaneous Luxation of the Eyeball.**—Levin's patient is a corpulent man with a tendency to exophthalmos since youth, noticeable also in other members of the family. One night he was awakened by a violent pain in his eye and he found that the eyeball protruded entirely from its socket. It was entirely outside of the lids, and he pushed it back into place with his fingers. This spontaneous luxation of the eyeball recurred repeatedly, affecting sometimes one eye and then the other. One of the eyeballs is liable to drop out in this way if he bends his head over far to one side, the spasmodic contraction of the lids behind the eyeball keeping it from spontaneous reposition. The vision is not affected by these spontaneous luxations, which are probably the result of vascular congestion in the veins of the orbit. Treatment was directed to relieving the tendency to congestions and varices and to controlling the eyes by keeping them bandaged at night. The patient found the bandaging so annoying that tarsorrhaphy is under consideration to make the palpebral fissure too small to allow protrusion of the eyeball.

67. **Cardiac Neuroses and Superposed Dilatation.**—Franze has observed a few cases of dilatation of the heart on both sides due to a neurosis of the heart or blood vessels or both. The patients were generally young or middle-aged and had complained of neurasthenic symptoms for some time previously, to which were finally added symptoms of a neurosis of heart or vessels or both, and the latter in time entailed unmistakable enlargement of the heart on both sides. The heart action suffered in consequence, but it could be modified by medication. The dilatation aggravated the other troubles and was important both for therapeutics and prognosis. He cites the particulars of a few cases and discusses the modus operandi of the dilatation. The sympathetic system is usually responsible for these neuroses of the heart, and this explains the curative action of electricity correctly applied in such cases. When the systole is feeble for a certain length of time, the inevitable result will be dilatation of the ventricles. Rehfisch and Colbeck have already suggested that nervous heart disturbances might entail organic changes. Prolonged decrease in the energy of the contractions of the heart must entail dilatation of the ventricles from the pressure of the accumulating blood within. The heart responds to stimuli differently from other muscles. Either it does not respond at all or it exerts its maximal energy. The smallest excitation produces the maximal functional response. Franze adds that the dilatation resulting from pathologic reflex or other excitation yields to appropriate dietetic and physical measures, especially to an individualized electrotherapy with the alternating current or "four-cell baths" in combination with carbonated thermal saline baths. In case of neuroses of the heart or vessels inquiry should be made for local foci in the abdomen or pelvis, especially in the urogenital tract in men and in the uterus or

adnexa in women. If a focus can be discovered, then the neurosis may be accepted as a reflex phenomenon by intermediation of the sympathetic. Also in all cases of general neurasthenia with nervous cardiac disturbances, the participation of the great sympathetic plexuses and ganglia should be suspected as the source of the pathologic irritation.

68. **Hemorrhagic Form of Cirrhosis of Liver.**—Aldor relates the history of 4 cases, some under observation for four years. His experience suggests that this affection is possibly identical with the syndrome known as Banti's disease. The special features of his cases were the absence of ascites and of meteorism, as well as of digestive disturbances and the recurrence of hemorrhages. In 2 cases they occurred as hematemesis, in 1 as enterorrhagia and in another as epistaxis. In some of the cases the spleen was not much enlarged and an extensive collateral circulation between the portal vein and the vena cava was surmised. In other cases the spleen was very large. Aldor is inclined to regard the hemorrhages as a kind of compensatory process. The resulting anemia was very protracted, but the patients recovered their previous strength after each hemorrhage with surprising promptness.

69. **Puncture of Testicle in Diagnosis of Azoospermia.**—Posner believes that the production of spermatozoa continues unchecked, although the passages for their outward flow may have been obstructed for years. It is extremely probable that under normal conditions a certain proportion of the spermatozoa die in the testicles and are absorbed, possibly supplying some element to the organism needed in the general metabolism. The question whether the testicles are still functioning normally is, therefor, of great importance, as operative intervention, opening a passageway for the spermatozoa to escape, will cure many a case of apparent irremediable azoospermia. To determine this question, Posner punctures the testicle with a Pravaz needle. It is a very simple and harmless procedure, without the slightest inconveniences. If the findings are negative he punctures again, as negative findings are sometimes encountered in healthy persons. He aspirates only enough fluid to spread on a glass for microscopic examination. It is difficult to obtain more than this, except in case of hydrocele or cystic enlargement of the tubuli seminiferi. The May-Grünwald stain shows up the spermatozoa well, but is not absolutely necessary. Posner has thus punctured the testicle in 17 cases, and among 12 patients who had epididymitis from seven to twelve years previously spermatozoa were found in all but 2, while, with a single exception, none were found in the 5 patients whose epididymitis dated from twelve to twenty-six years before. The exception was a man who had living spermatozoa, although the ducts had been obstructed by epididymitis seventeen years previously. The spermatozoa were found in lively motion in one case, contrary to the general assumption that they do not become lively until they feel the effect of the prostatic fluid. Posner's previous communication on the value of surgical treatment to remove the obstacle causing apparent azoospermia was published in the *Deutsche med. Wochft.* last year, and was summarized in The Journal, page 638 of volume xliii.

70. **Treatment of Intestinal Affections in Infants.**—Salge merely reviews the present status of treatment of intestinal affections. In those due to too much food at a time and too short intervals between, without organic changes, he states that all food should be stopped and only as much weak, black tea given as corresponds to the amounts of the preceding feedings. If this starving for twenty-four hours is not enough, calomel can be given in doses of from .02 to .05 gm. every two hours until three doses have been taken. It is best to substitute some other food for the milk for a time afterward. When the stools become less fluid and generally dark-brown in color, after three days of flour feeding, milk can be resumed. If a tendency to vomiting and loss of appetite persists, the motor function of the stomach should be examined. This can be done by siphoning out the stomach three hours after a meal to find whether it is empty or contains free hydrochloric acid. If not empty, the stomach should be rinsed, which is a simple matter in an infant. A 1 per cent. solution of Carlsbad salts is admirable for the purpose. The appetite sometimes returns surprisingly after lavage of the stomach, and he sometimes uses it for this indication alone. When the anorexia is persistent, pepsin or hydrochloric acid or bitters might be tried or a mixture of 1 part tincture of strychnin and 2 parts of fluid extract of condurango in 10 parts of tincture of wine of rhubarb. Five drops of this mixture are given three times a day, fifteen minutes before the meal. When the dyspeptic disturbances are severe, the symptoms of intestinal catarrh suggest a serious intoxication of the system. Here the main indication is to sustain the heart. If the tendency to collapse can be controlled, the children recover in apparently desperate cases. Large doses of camphor are required, from .1 to .2 gm. at first and then from .05 to .1 gm. every two hours. All food should be suspended and only enough tea given to moisten the mouth. The loss of water is compensated by subcutaneous saline infusions twice a day, injecting from 120 to 150 c.c. of a .9 per cent. salt solution, or, better still, a solution of .5 salt and .5 sodium bicarbonate in 100 parts water. The high temperature is combated by wrapping the child from head to feet in a sheet wrung out of cold water (not room temperature) and covering with a blanket. After from ten to fifteen minutes another sheet is applied in the same way, repeating the procedure about five times. In case of collapse the child must be artificially warmed, even putting it in an incubator if necessary. After the infant has recuperated from the tendency to collapse, feeding should begin again, but without any fat in the food. Breast milk is liable to contain too much fat, and the child may relapse if placed at the breast, the collapse being fatal in this case. Salge has had excellent results from the use of human milk from which the fat has been removed. This is possible only when an abundance of human milk is at disposal, but it has saved many infants in his experience who otherwise would have been doomed. When human milk with fat removed can not be obtained, the tea should be continued for days and the breast milk should be drawn and given by the teaspoonful, in small amounts, not more than 50 c.c. the first days and increasing this amount very slowly and cautiously. The result is not so certain as when skimmed breast milk can be given. If no breast milk is available the tea diet should be continued for two or three days and then thin flour gruel or whey added. Milk should be resumed very cautiously, and buttermilk and diluted milk made with some preparation of malt should be given during convalescence. Cholera infantum is merely a severe form of intestinal catarrh and the indications are the same. Nephritis is the principal complication to be feared.

71. **Subcutaneous Omentopexy.**—Narath thinks that all the advantages of the Talma operation can be secured by merely drawing up a piece of the omentum and fastening it in a subcutaneous pocket. His experience has shown that this answers perfectly the purpose of inducing extensive anastomoses and thus relieving the ascites. He incises above the umbilicus on the median line under Schleich local anesthesia. The ascitic fluid is evacuated, its escape from the deep-lying parts being insured by suction through metal catheters in rubber tubes inserted into the small pelvis and in the hypochondrium and lumbar regions. The greater omentum is seized and a thick tuft pulled out of the wound, but without altering the position of or pulling on the transverse colon. A part should be chosen containing as many blood vessels as possible, and it should be the thickness of one or two finger breadths. The incision should then be sutured to allow space only for the tuft of omentum without compression. This portion of the omentum is then sutured to the parietal peritoneum and linea alba, avoiding the veins. A pocket in the subcutaneous tissue

is then hollowed out, and the tuft of omentum—from 10 to 15 cm. long—is laid in this hollow. No further fixation is required. The results have been eminently satisfactory. The omentum is thus transplanted into a region particularly rich in blood vessels, and by the increased intra-abdominal pressure the blood is forced at once from the omentum into the developing anastomoses, as can be easily seen on inspection.

72. Carbolic Acid and Camphor in Treatment of Infected Wounds.—Chlumsky is enthusiastic over the fine results obtained in the treatment of infected wounds with a mixture of pure carbolic acid and camphor. The camphor seems to neutralize the caustic action of the carbolic acid so that the mixture feels like mere oil or chloroform when poured on the hand. His formula is: Carbolic acid 30 parts, camphor 60 parts, and alcohol to make 100. He has been using this mixture for six years in treatment of surgical infections, erysipelas, phlegmons, tuberculous fistulas, furuncles, etc. He evacuates the pus and pours the mixture into the cavity, as much as 30 to 50 gm. in a deep abscess, without any disagreeable by-effects. Infected wounds are rinsed with the mixture, and a tampon saturated with it is laid in the wound until suppuration is diminishing, when the mixture is poured in. In erysipelas the affected area and the surrounding skin are swabbed with the mixture from two to five times a day. Old patches are surrounded by a bank of cotton saturated with the mixture and covered with oiled silk or waxed paper. In recent cases the redness subsides and the trouble is aborted in a few hours. The mixture keeps perfectly if evaporation of the camphor is prevented.

74. Flaps for Repair of Defects in Skin.—Hagen describes two cases in which he covered a large defect with a flap from the same limb far above. The outer end of the pedunculated flap was turned over and sutured in the upper part of the defect below. The raw surface of the flap was thus turned upward, except at the end where it had been sutured in place in the defect. A roll of gauze under the arch formed by the flap kept it from falling and oiled silk on the raw surface kept it from drying up. In six days the sutured end had healed in place and the base of the flap was gradually divided and brought down to complete the covering of the defect below by the fourteenth day. In less than a month it had healed completely in place, the only trace of the defect being a linear scar around the edges of the transplanted flap.

77. Remote Results of Cancer Operations at Budapest.—Dollinger's statistics embrace 193 cases of cancer with 33 operations for recurrence. Of this number the remote results are known after three years in 150 patients and 40 per cent. have been free from recurrence. The history of 80 patients is known for five years, and of this number 41.23 per cent. have been free from recurrence. The results will be better in the next decade, as the technic of operations for cancer is being constantly improved.

79. Treatment of Idiopathic Edema.—Meyer's diagrams and clinical histories demonstrate the great importance of restricting the intake of salt in the food when an infant shows indications of idiopathic edema. Artificial foods should be avoided as they generally contain more or less salt. He relates the results of tests and the great influence on the elimination of urine during these periods in which salt, sodium phosphate or distilled water were given.

82. Photo-Salve Treatment.—Axmann reports favorable results in various cutaneous affections from the use of a salve applied to the parts which were then exposed to heat rays from an electric light or in an electric-light bath. The composition of the salve rendered it impermeable to the active rays, but its therapeutic action was unmistakably promoted by the heat.

87. Permeability of Tubes for Injected Fluids.—Buttenberg's experiments on 27 cadavers showed that the tubes are permeable in the majority of cases, but that only a small amount of the injected fluid can pass through them. He advises the use of a reliable two-way catheter, and that the injection should be made with a pressure corresponding to a height of less than a meter. Very poisonous disinfectants, such as corrosive sublimate, should not be used for uterine injections. It is not enough to rinse the catheter and tubes in the disinfectant. They should be allowed to stand in them as long as possible, while other preparations are being made, hands disinfected, etc., and should be rinsed out with boiling water to warm them just before use. The presence of inflammation should contraindicate the use of caustics and strong poisons.

88. Treatment of Neurasthenics and Neurotics in the Mountains.—Jessen practices at Davos, in Switzerland, and states that the air of the mountains there contains so much radioactivity that he was able to collect sufficient to inhibit the growth of the *Staphylococcus aureus* and the *B. prodigiosus.* He presents an array of arguments to show that the stimulating effect of a mountain climate is particularly beneficial in certain purely functional nervous affections, results being attained which are not realized anywhere else. Brilliant results are obtained in acquired neurasthenia, in nervous stomach disturbances, hyperacidity and cardiac neuroses. Affections with an organic basis are not adapted for this mountain cure, but latent pulmonary tuberculosis frequently hides under the picture of neurasthenia. The depression, abnormal irritability, hyperacid disturbances and cardiac neuroses of the heart may be the only evidences of the insidious lung process for which the mountain climate is especially adapted. Fine results are also obtainable in diabetes, exophthalmic goiter, asthma, chlorosis, etc. The only requisite is that the patients are still capable of responding to stimuli. He quotes the remark made by certain persons that they never lie down in bed at Davos without a shudder at the possible danger of tuberculosis contagion, and presents evidence to prove that the prophylactic measures and disinfection carried on there to such perfection render the town much safer from tuberculosis contagion than any large city. The mortality from tuberculosis among the natives is far less than it was before the place became a health resort.

92. Catalytic Influencing of Oxidation of Sugar.—In this second communication Schade discusses the catalysis of sugar combustion in the economy of organic nature. He surmised that the blood—as the intermediate agent of the oxidation effects—besides the rôle of transporting the oxygen, also plays a part in promoting the receptivity of the intraorganic sugar so that it takes up with greater avidity the oxygen brought by the blood. This assumption has been confirmed by his discovery that a single drop of human blood, or mere traces, placed on a lump of ordinary cane sugar, even before it is dry, renders it highly combustible. If the sugar is then held in an alcohol flame it lights at once and burns furiously, sometimes even explosively. Grape sugar behaves in the same way, but not with such intensity. The oxidability of the sugar is materially enhanced by contact with the blood. Further tests showed that other substances have this same power of catalytic influencing of sugar. If a lump of sugar is dipped in cigar ashes or brought into contact with the kernels of fruit or grains or similar vegetable product, coffee, tea, pepper, cocoa, etc., it burns with great energy when touched with a lighted match. All these substances are good catalyzers. Their catalyzing property is not affected by cooking and differs in other respects from that of the oxydases. He, therefore, proposes for this group the term "oxydators." He thinks that his researches promise to reveal the *modus operandi* of the action of ferments. He has succeeded in tracing the oxygen-transporting components of hemoglobin through the various steps of the decomposition products to the terminal stage of the metallic iron. Not only hemoglobin, but also its hematin, its ash, its iron salts and the pure metallic iron have all demonstrated their capacity for transporting oxygen. The organic envelope as a condition *sine qua non* for the catalysis of hemoglobin and of the glycolytic enzymes has been done away with by these researches. They have shown that part of the specific ferment activity can be accomplished by their simplest inorganic elements as a catalytic effect.

94. Ultra-Violet Rays in Therapeutics.—Axmann thinks that the ultraviolet rays have marked chemical action, and that these alone can be utilized for therapeutic purposes. The advantages derived from red glass, blue glass, etc., are due to the fact that they change the rays passing through them into chemically active short wave rays. He reports his experience with lamps made to produce these rays alone. It has been extremely favorable in alopecia, chronic eczema, acne, sycosis, erysipelas and in cases of suppurating wounds. He noticed that venous blood after long exposure to the air turned a bright red when brought near the ultraviolet rays from his lamp. The coagulation of the blood was also accelerated. He explains these phenomena as due to the nascent ozone, and states that fresh and suppurating wounds behave under the rays as if they had been swabbed with hydrogen dioxid. He has thus treated 10 patients with ulcers on the feet of from six weeks' to three years' duration. The exposures were half an hour in length, and the ulcers all healed in four weeks at farthest, from three to eight exposures being made. In one of the recent cases the ulcer healed under the physician's eyes in two exposures. The chemical action of the rays may be enhanced, he thinks, by sensitizing the tissues with some chemical. He is now experimenting with chlorin. Chemical processes are the forces at work and bearers of the energy.

95. Castration in Cases of Mammary Cancer.—Schinzinger states that he proposed, in 1889, the advisability of castration in case of cancer of the breast. Cancer seems to be more malignant in young women, and his idea was that castration would hasten the atrophy of the mammary glands and thus reduce the extra malignity of the neoplasm. He reviews the literature on the subject, but has had no opportunity to carry his idea into execution. He would not restrict it to inoperable cases, but would castrate on the first discovery of cancer. Out of his 80 cases of mammary cancer since 1889 three were in men. Two of the men had sisters or a daughter with carcinoma *of the breast, neck or abdomen.*

98. Intestinal Mucus Secretion.—Schütz concludes his article with the statement that purely neurogenic mucous hypersecretion is of rare occurrence. It can be assumed when the excessive secretion occurs spasmodically, the amounts being moderate or minimal during the interval, and when the hypersecretion is accompanied by nervous symptoms or appears after nervous excitement. As a rule, however, there is always some catarrhal condition underlying the apparently purely nervous affection.

PSEUDO-SCLEROSIS (DIFFUSE SCLEROSIS),

WITH THE REPORT OF A CASE WITH NECROPSY.[*]

CHARLES S. POTTS, M.D.

Associate in Neurology at the University of Pennsylvania, Neurologist to the Philadelphia General Hospital.

WITH PATHOLOGIC REPORT AND REMARKS.

WILLIAM G. SPILLER, M.D.

Professor of Neuropathology and Associate Professor of Neurology in the University of Pennsylvania; Neurologist to the Philadelphia General Hospital.

PHILADELPHIA.

In 1883 Westphal[1] reported two cases presenting a symptom-complex resembling that of multiple sclerosis, but in which microscopic examination of the brain and cord gave negative results. To this condition was given the name pseudo-sclerosis. Since this time a number of cases (14) presenting this condition have been reported, mostly by German observers. It will be noted in reading the abstracts of these cases, which are given below, that the brain and cord in a number of them were unusually firm. A similar condition of hardness, although possibly more marked, is observed in another group of cases also presenting a symptom-complex resembling that of multiple sclerosis, in which microscopic examination of the brain and cord shows a proliferation of neuroglia and vascular disease. To this condition the term diffuse sclerosis has been applied, and a number of cases have been reported, mostly by German authors.

As will be shown further on, some authorities are coming to the opinion that the same pathologic condition is present in both pseudo-sclerosis and diffuse sclerosis, the former being merely a milder degree of the latter. To call attention to this possible relationship is one of the objects of this paper.

The pathologic condition now known as diffuse sclerosis has been frequently noted in the past, especially in the brains of idiots, and cases occurring in adults were reported years ago, although not under this title; but it is only recently that attempts have been made to erect on this basis a distinct disease.

Probably the first case was reported in 1849 by Duplay[2] to the Biologic Society of Paris. The patient had suffered for a number of years with paralysis and contractures of the lower extremities, probably brought on by overexertion and sexual excess. After a while the bladder, rectum and tongue became paralyzed, the mental condition being reported as good. At the autopsy the internal membranes were found to be opaque, but not adherent to the cortex; the gray matter was normal, but two-thirds of the white matter was sclerosed, more so toward the ventricles. This condensation was equal in extent on both sides. The tissue was yellowish and cloudy. The optic chiasm and the striate bodies were also of greater consistency than normal. The cord was small and atrophic.

In 1854, under the title of "A Case of Cerebral Sclerosis," M. Hirsch[3] reported a case and stated that several others have reported cases of chronic induration of the brain tissue. His patient was a man, 53 years of age, who had been suffering for several years. At the autopsy the principal conditions found were an injection and infiltration of the pia-arachnoid, which was easily separated from the cortex, and a toughness and dirty-white color of the brain substance; there was very little cortex, the tough, dirty-white material taking its place; in some places the brain seemed cartilaginous. The ventricular lumen was small, the striate bodies and optic thalami were atrophic and tough. In the left frontal lobe several spots of sclerosis differing from the rest of the substance in luster were seen. The pons, medulla and peduncles were also indurated. The basilar arteries were sclerotic. The condition of the spinal cord was similar to that of the brain. The clinical symptoms were disturbances of sensation, headache, dizziness, disturbances of motion as convulsive movements and contractures, paralysis of one hypoglossal nerve and of the bladder and anal sphincters, and causeless laughter and crying.

The first American case was probably reported by Echeverria[4] in 1869. His patient was a man aged 69 years, who had been an epileptic. His symptoms for several months before his death consisted of dizziness when he attempted to walk, weakness of the tongue, and paralysis of the lower limbs with contractures and involuntary muscular contractions. There was also pain in the legs. A bedsore and an eruption of herpes zoster developed. At times he was confused, at other times he would lose the power of articulating and swallowing, while at other times these processes and his mentality were intact. At the autopsy, in addition to aneurism of each vertebral artery, the cortex of the brain was found to be anemic and yellowish, and the brain substance was sclerosed, especially along the superior and inferior marginal convolutions, and both sides of the fissure of Sylvius. The medulla and the cord were also involved. Microscopically, the nerve elements were found to be diminished in number, their places being taken by proliferating connective tissue cells and fibers.

After this some other cases were reported, notably by Kelp,[5] and in 1878 A. Strümpell[6] wrote an exhaustive paper on the subject. He defined it as a condition in which the abnormal hardness and consistency of the brain, as a whole or in its greater part is noticeable on macroscopic examination. As causes he mentions hypertrophy of the brain, usually associated with idiocy; atrophy of the brain, senility, alcoholism, saturnism, and acute and chronic inflammatory diseases. He reports a case in an alcoholic and believes the sclerosis to have been due to a chronic diffuse interstitial encephalitis. He concludes that a definite disease can not be described from the reported cases.

After Echeverria, probably the next American cases were reported by Bullard.[7] In 1897 Heubner[8] reported a case and endeavored to set up a definite clinical picture. He describes it as a disease characterized by the appearance of paralysis and psychic disturbances. A spastic paresis of the legs first develops, which gradually extends to the arms; at the same time apathy and dementia appear and may terminate in idiocy. In the end a general paralysis develops; in some cases dysarthria and dysphagia occur. Optic neuritis was seen in one case. Etiologically he believes that hereditary syphilis and cerebral trauma play active parts.

In 1900 H. Weiss[9] reported a case and gave an exhaustive description of the disease, with full bibliography. His patient was a woman, 37 years of age, who had had symptoms of acute meningitis, associated with a suppurating middle ear. Two years after this attack she developed stiffness and weakness of the legs, painful spasms, hesitating speech, emaciation, increase of all the reflexes, increased mechanical irritability of the muscles. There was no involvement of the cranial nerves, sphincters or of sensation. He lays especial stress on the universal rigor which developed whenever she attempted to move. This he described as follows: When quiet, all the voluntary muscles are flaccid, with probably a slightly higher tonicity than normal; as soon, however, as movement is attempted the muscles become rigid, and the rigidity slowly increases to a maximum and then decreases in the same way. This rigor can be produced also by passive movements. All the muscles (trunk, extremities, larynx, eye, etc.) are affected. Every movement is laborious, hesitating and dragging. Speech is difficult because of spasm of the vocal cords. In addition to these symptoms there was apathy and gradually developing dementia. He considered the condition to be due to the previous meningitis. According to Weiss, other symptoms which may be present are vertigo, headache, ideas of grandeur as in paretic dementia, sudden changes of mood, the patient passing from a happy state into crying attacks; strabismus, inequality of the pupils, myosis, slow reaction of the iris to light, fibrillary tremors, general muscular atrophy, and tremor on movement.

In discussing the etiology, he states that the cases are to be divided into those existing before birth and those arising after birth. In the former class, the anatomic changes show that the child has had meningitis in utero associated with cerebritis, the nerve elements having been destroyed in large numbers. A meningoencephalitis can also produce it in an adult; other factors are syphilis, either acquired or hereditary, individual predisposition, heredity, overexertion, traumatism, alcohol and epilepsy.

Patient.—The patient whose case is now reported was admitted to the Philadelphia General Hospital Oct. 28, 1900. The man was a negro, 57 years of age, and a laborer by occupation. His chief complaint was "tremor and weakness of the extremities."

History.—There was nothing to note in the family history. Until six months before admission, when his present illness began, he had been a healthy and hard-working man. Until four years previous to admission alcohol had been used to excess. Syphilis was denied. The autopsy, however, showed that probably he had had it. Gonorrhea he had had once. The first symptoms noticed were progressive loss of strength, staggering and a tendency to trip over small objects. He stated that at times he became giddy and had fallen. He had suffered from dyspnea on exertion for the past twenty years.

Examination.—The heart, lungs and other viscera were apparently normal. The urine was normal. There was ataxia of both arms, also a coarse tremor, which was intensified by voluntary movements, such as lifting a glass. The gait was slightly staggering and spastic. The knee-jerks were increased, ankle clonus was absent, but the Babinski reflex was present on the right side. The pupils were equal, did not react to light, but did in accommodation. There was no other involvement of any of the cranial nerves nor of the bladder or rectum. Sensation was normal. A diagnosis of multiple sclerosis was made.

March 1, 1901, the following notes were made: There is no scanning speech. Tremor of the tongue is not present when the tongue is protruded, but there is a marked tremor of the muscles of the upper part of the face at this time. When the arms are extended a coarse tremor is developed. Extension of the legs also causes a tremor to develop in them, which ceases when the patient attempts to touch anything with his foot. This movement, however, is ataxic and there is slight ataxia of both arms. Nystagmus is absent. The gait and station are fairly good. The knee-jerks are much exaggerated, and ankle clonus is present on the right side. The Babinski reflex can not be elicited.

July 5, 1902, it was noted that for several days previously the patient had been noisy and had refused to eat, asserting that the food had been poisoned. By July 19 these symptoms had disappeared. This was the only time that the patient's mental condition occasioned any comment, he having been up and about since admission. July 28 he was suddenly taken with a convulsion, which lasted an hour. He then became comatose and remained so until he died, on July 29.

Assuming that diffuse sclerosis and pseudo-sclerosis are distinct conditions, Frankl-Hochwart[10] has made an elaborate attempt to formulate points of distinction in their symptomatology. He compared 13 cases of so-called pseudo-sclerosis with 22 cases of diffuse sclerosis with the following results:

ETIOLOGY.

1. *Age.*—The majority of cases of both occur in early life; only 3 cases of diffuse sclerosis are recorded in which the symptoms appeared after 40.

2. *Heredity.*—A history of various forms of nervous disease in the family may be obtained in either condition. This, however, seems to be somewhat more frequent in pseudo-sclerosis than in diffuse sclerosis.

3. *Traumatism.*—No case of pseudo-sclerosis can be traced to this. Eight cases of diffuse sclerosis have such a history; 5 head injuries, 1 fall from a tree, 1 a lightning stroke, and 1 difficult labor.

4. *Lead Poisoning, Syphilis and Typhoid Fever.*—These are mentioned as causes of pseudo-sclerosis; alcoholism, meningitis, nephritis and syphilis among those of diffuse sclerosis.

SYMPTOMATOLOGY.

Paralytic Symptoms.—These are the same in both conditions, i. e., either paralysis or paresis, which may be transitory and change its location; it may be hemiplegic in type.

[10] "Zur Kenntniss der Pseudo-Sclerose," Obersteiner's Arbeiten, 1903, x, p. 1. (A bibliography is appended in the monograph.)

The Gait.—Either an ataxic or spastic gait is common to both affections, in some cases of diffuse sclerosis, however, walking is impossible on account of the spasms caused by the effort to walk.

Contractures.—These are common to both conditions and may be either transitory or permanent. The muscles of the back of the neck may be affected.

Tremor.—This is constantly present in pseudo-sclerosis and in two-thirds of the cases of diffuse sclerosis. The intention tremor is the more common; in pseudo-sclerosis this is in the nature of a to-and-fro movement, which does not occur in diffuse sclerosis. The head, face and tongue may also be the seat of tremor.

Pain and Paresthesiæ.—These occur equally.

Mentality.—In pseudo-sclerosis mental disturbances are the rule but not as common as in diffuse sclerosis, not one of the patients with this latter condition having a normal mind. Epilepsy, headache, vertigo, causeless laughter and crying, syncope and apoplexy occur equally in the two affections. Paralysis of the tongue, either bilateral or unilateral, is noted more frequently in diffuse sclerosis.

Tendon Reflexes.—These are increased equally in both conditions. Clonus is more frequent in diffuse sclerosis.

Speech Disturbances.—These are more marked in diffuse sclerosis (80 per cent.). The speech may be either scanning, dragging or indistinct. Aphasia may also occur in diffuse sclerosis, but has not occurred in pseudo-sclerosis.

Affections of Other Nerves.—The cranial nerves are more frequently affected in diffuse sclerosis than they are in pseudo-sclerosis. In the former optic neuritis, optic atrophy, optic pallor, amblyopia with normal fundus, hemianopsia, transitory diplopia, and strabismus have each been noted once; nystagmus and abducens paralysis, three times. Pupillary disturbances, i. e., either inequality, slow reaction or no reaction, may be present in diffuse sclerosis, but in pseudo-sclerosis the pupils react normally. In 11 cases of diffuse sclerosis facial paralysis occurred; this was never seen in pseudo-sclerosis. Hypesthesia and hypalgesia were present in 9 cases of diffuse sclerosis, but in only 1 of pseudo-sclerosis. Forced movements and tic occurred in a number of cases of diffuse sclerosis, but in only 3 of pseudo-sclerosis. Trophic and vasomotor disturbances and muscular atrophy are much more common in diffuse sclerosis. This is also true of bladder and rectal disturbances. Remissions occur in pseudo-sclerosis, but do not in diffuse sclerosis. The duration of the two affections is about equal.

It will be noted that the symptoms of these conditions are very similar, and it seems possible that, clinically as well as pathologically, as will be shown further on, this elaborate attempt to distinguish between the two diseases may be to make a distinction without much of a difference. As has been said, some authorities seem to be tending to this view.

Thus A. Strümpell,[11] in reporting 2 cases of pseudo-sclerosis, mentions that out of 4 cases of this disorder reported by him a peculiar anomaly which seemed to connect this disease with diffuse sclerosis had existed twice, i. e., the white matter was anemic and hard. This was also noted by Westphal in one of his cases. Strümpell concludes as follows: We have to do with the picture of a disease which in its details and in its chronic course resembles markedly multiple sclerosis, but its pathologic basis has never been found in any case. In most of the sections thus far made, nothing has been found. . . . In some of these cases a peculiar dense, leathery consistency of some parts of the brain substance has been observed. No histologic cause for this is known. Such cases seem to act as transitional cases between pseudo-sclerosis and those in which the entire cerebrum possesses this dense, tough consistency, and which have been spoken of as instances of diffuse sclerosis.

Oppenheim[12] remarks that in many of its symptoms diffuse sclerosis resembles pseudo-sclerosis, in which anatomically there is an increased consistence of more or less of the tissues, so that even anatomically it is difficult to draw a distinct line between pseudo-sclerosis and diffuse sclerosis. He concludes as follows: There is a certain form of disease resembling multiple sclerosis which occurs especially in childhood, although it may appear later. It is characterized by early dementia, a special variety of tremor and disturbance of speech, muscle tremor, the absence of nystagmus, of affection of the optic nerve and of tendon phenomena. This condition is known as pseudo-sclerosis. Anatomically it is either absolutely negative or there may be a slight degree of diffuse cerebral sclerosis. The same symptom-complex, or one approaching more closely to dementia paralytica, may be associated with a true diffuse cerebral sclerosis and degeneration of the pyramidal tracts. This condition can not be diagnosed during life. The combination, occurring in childhood, of progressive spastic paralysis with progressive dementia may arouse the suspicion that such a diffuse sclerosis exists. On account of the rarity of multiple sclerosis in early childhood it is proper to make, in such patients, a probable diagnosis of diffuse sclerosis, but in such cases the question must always be left open, whether pseudo-sclerosis or diffuse sclerosis exists. These conditions must be differentiated from multiple sclerosis and paretic dementia. Weiss says that the absence of nystagmus, changes in the eye-grounds, sensory disturbances and localized muscular atrophy distinguish diffuse sclerosis from multiple sclerosis; but a reference to Frankl-Hochwart's table will show that all of these symptoms, with the exception of the last, may be present in diffuse sclerosis, though rarely.

It is evident from the foregoing that so far as our present knowledge goes the diagnosis of this condition during life is exceedingly doubtful. The peculiar features of the case reported are the advanced age of 53 years when the symptoms began, the absence until late of marked mental changes, the absence of marked speech disturbances, and the presence of the Argyll-Robertson pupil. His symptoms differed from those usually found in multiple sclerosis, in the absence of nystagmus, great increase of the tendon reflexes, and scanning speech. It may be worthy of note that until four years previous to the onset of the symptoms the patient had used alcohol freely.

PATHOLOGIC REPORT AND REMARKS BY DR. SPILLER.

Sharp distinctions between the pseudo-sclerosis and the diffuse sclerosis are impossible either by means of the symptoms or the pathologic findings. It is true that Strümpell and Frankl-Hochwart made the diagnosis of pseudo-sclerosis each in one case during the life of the patient; Strümpell did not form the correct diagnosis until he found he had erred in a case with similar symptoms that came to necropsy, and Frankl-

[12] Nervous Diseases, 4th Edition, p. 359.

Hochwart at first believed that his case was one of multiple sclerosis. It is not surprising, therefore, that when the patient described by Dr. Potts was seen soon after his admission to the hospital in 1900 by Dr. C. K. Mills and myself, he was supposed by us to have multiple sclerosis.

In pseudo-sclerosis the findings should be negative, and in the diffuse sclerosis a more or less intense proliferation of neuroglia throughout the brain and spinal cord should be present, but transitional forms between the two disorders have been established by the pathologic findings. The neurogliar proliferation, however, does not form the distinct areas of degeneration seen in multiple sclerosis.

I have found the reports of 14 cases of pseudo-sclerosis with necropsy, and yet the findings were not negative in all of these. In one of Westphal's cases the brain was very firm (Case 1), as it was also in one of Strümpell's cases (Case 2), and in one of Langer's cases (Case 1). Frankl-Hochwart regards such cases and the case of Burk as transitional forms. In Bäumlin's case with necropsy there were slight spinal meningitis and some loss of nerve fibers in the spinal cord. In a number of cases of pseudo-sclerosis the brain was not examined microscopically. In two of Strümpell's cases the crossed pyramidal tracts appeared to be slightly degenerated (Cases 1 and 2). In Frankl-Hochwart's case the frontal lobe was atrophic. In one of Fickler's cases the cerebral gyri were diminutive, the pons and medulla oblongata were very small, the crossed pyramidal tracts were less deeply stained and contained more neuroglia tissue than was found elsewhere in the white matter. In Fickler's other case the pons and medulla oblongata were unusually small and hard.

Strümpell, in reporting the negative findings of his third case, remarks that pathologic changes in the central nervous system must have existed, but they were not of so gross a character that they could be detected by the usual histologic methods. Schultze found thickened vessels and some swollen axis cylinders.

It may be well to give the findings in the cases of pseudo-sclerosis with necropsy. With one exception (Babinski) I have obtained the original reports of these cases and have abstracted the findings.

1. In C. Westphal's[1] first case the gyri were small, especially in the temporal and occipital lobes, the white matter of the brain was anemic and very hard, especially in the posterior portions. The microscopic examination of this case was negative.

2. Westphal's Case 2. Microscopically and macroscopically the central nervous system was normal.

Fickler includes the second case of Langer[13] as one of pseudo-sclerosis, but Strümpell thinks both cases probably belong to this group.

3. In Langer's first case the brain substance was hard, but no microscopic changes were found in the central nervous system. The patient had had convulsions and had been unable to swallow, and Langer says that his condition resembled hydrophobia when he attempted to swallow.

4. In his second case the symptoms and pathologic study are very briefly reported. No changes were found in the central nervous system.

5. Babinski.[14] The cerebral pia was a little edematous. The brain and spinal cord appeared to be normal. Microscopically the tissue was normal, except that there was some slight sclerosis in certain places. The brain was not examined microscopically.

6. Francotte.[15] Macroscopically and microscopically nothing abnormal was seen. The brain and cord were not examined by the Marchi method.

7. In Strümpell's[11] first case the consistency of the brain was normal; sections from the spinal cord stained by the Marchi method showed a moderate amount of black dots scattered diffusely, but perhaps a little more numerously in the crossed pyramidal tracts. The crossed pyramidal tracts in the cervical region were less deeply stained, and there seemed to be a slight loss of nerve fibers in these areas.

8. In his second case the brain was remarkably hard and was almost of the consistency of leather in the occipital lobe. The lateral ventricles were dilated. The crossed pyramidal tracts seemed slightly degenerated in the upper part of the cord. The tissue from the brain, although it had felt so hard, appeared to be normal under the microscope. The Marchi method probably was not employed in this case.

Strümpell regards the cases with hardening of the central nervous system as transitional forms between pseudo-sclerosis and diffuse sclerosis, and he thinks syphilis may be an important cause of both processes.

9. In Strümpell's third case the central nervous system was normal macroscopically and microscopically. Marchi's method was not employed.

10. F. Shultze[16] says, in the brief report of his case, that he found thickened vessels and some swollen axis cylinders. The cerebral cortex was not examined microscopically.

11. Bäumlin[17] found chronic leptomeningitis of the brain and some spinal meningitis, slight loss of nerve fibers in the cord, congestion of the brain, and slight dilatation of the lateral ventricles. The brain was not examined microscopically. Marchi's method was not used.

12. Frankl-Hochwart[10] found the Pacchionian granulations very numerous in his case. The frontal lobe was atrophic, but otherwise there were no macroscopic or microscopic alterations.

13. Fickler[18] (Case 1) observed sclerosis of basal vessels, and the fissures of the cerebrum were deep and the gyri small, the pons and medulla oblongata were very small and hard, and the pyramidal tracts were slightly degenerated. The brain and spinal cord were examined microscopically, but not by the method of Marchi.

14. Fickler (Case 2.) The pons and medulla oblongata were small and hard. Microscopic examination does not appear to have been made.

We may compare the findings in these cases of pseudo-sclerosis with those obtained by Hugo Weiss[9] in a case of diffuse sclerosis. The central nervous system was very hard. The brain on microscopic examination appeared to be normal. The neuroglia was proliferated in the spinal cord, and numerous spider cells were found. The septa were two or three times the usual thickness. The walls of the vessels, even of the smaller vessels, were thickened, and perivascular cellular infiltration was present. The nerve cells were normal.

The findings in other cases of diffuse sclerosis as given by Weiss have been: Distinct proliferation of the neuroglia, greater at some parts of the central nervous system than at others; perivascular round-cell infiltration, many spider cells, thickened and numerically increased vessels, and chronic meningitis. Degeneration of distinct systems of fibers does not occur.

It is evident, therefore, that sharp distinctions between the findings of pseudo-sclerosis and those of diffuse sclerosis can not be made, and that the differences are probably chiefly in the degree of the alteration and not in the character of the alteration. The unusual firmness described in some of the cases of pseudo-sclerosis must be caused by a proliferation of the neuroglia, even though this proliferation can not be detected by the microscope.

NECROPSY.

The case that Dr. Potts and I report may be regarded as one of pseudo-sclerosis, or at least as a transitional form. It is probably the first case that has been observed in a colored person. The necropsy was made by Dr. F. P. Gay, July 29, 1902. The pathologic diagnosis was hardening of the brain and spinal cord; chronic diffuse nephritis; gummata of liver; acute serous pericarditis; acute fibrinous pleurisy.

The brain was extremely hard in all parts and the blood vessels throughout were very prominent. On section, the brain was markedly firm in both the gray and white matter. There was no evidence of gross pathologic lesions. The white substance was more firm than the gray. The cortex was slightly increased in thickness and was homogeneous and extremely firm in consistence. The injection of the capillary vessels was extremely marked throughout the brain. The basilar artery was rigid.

The spinal cord was extremely firm and showed no areas of degeneration. The entire brain, when removed from the cadaver, felt as though it had been partially hardened by some fluid.

The microscopic examination was made by me. The cerebral pia was slightly thickened and showed an unimportant round-cell infiltration. Sections from the para-central lobule stained by the Weigert hematoxylin or acid-fuchsin method presented no distinct signs of degeneration; but some of the small capillaries within this part of the brain were thickened and some were calcified. The cells of Betz, stained by thionin, were normal, except that occasionally slight diffuse staining was detected. Slight round-cell infiltration was seen about some of the small vessels within the paracentral lobule, but this was not important. In some parts of the paracentral lobule hemorrhages within the perivascular spaces were found.

The medulla oblongata appeared to be normal, both by the Weigert hematoxylin and the acid-fuchsin stains.

The neuroglia of the white matter of the spinal cord was possibly slightly increased in amount, and occasionally a somewhat swollen axis cylinder was found. The nerve cells of the anterior horns stained by thionin appeared to be normal in the cervical and lumbar regions. No alteration could be detected in the spinal cord by the Weigert hematoxylin method, and there was no round-cell infiltration within the spinal cord or spinal pia. The Marchi sections of the cord showed a very few black dots in the crossed pyramidal tracts, so few that they are of questionable importance, and were not unlike what Strümpell found in one case.

NOTE.—Since this paper was prepared a case of diffuse sclerosis has been reported by Rebizzi.[19] He expresses opinions regarding the relation of the pseudosclerosis to the diffuse sclerosis similar to those set forth in this paper.

Feeding Patients in the First Stage of Labor.—The *Canadian Nurse* states that patients are less exhausted after labor if they can be induced to take a little easily digested nourishment during the first stage; and that tea, hot milk or chicken broth seldom interferes with the subsequent administration of chloroform, should this be necessary.

CANCER OF THE BREAST.

END RESULTS OF 100 OPERATIONS.

HOMER GAGE, M.D.
WORCESTER, MASS.

Five years ago this winter, I reported[1] the results of my operations on the cancerous breast, with the subsequent history of each of 46 cases. To this record I now desire to add 62 cases of cancer of the breast, all operated on prior to 1904, 42 of which were done before 1902, and have, therefore, passed the traditional three-year period.

Since the reading of the earlier paper, little has been added to our knowledge of the disease itself, nor has any substantial advance been made in the means of preventing or controlling it. The subject of the general distribution and prevalence of cancer has been much discussed, and the deaths from cancer certainly seem to be increasing steadily from year to year. This opinion is derived from the results of postmortem examinations made at the large clinics of continental Europe, as well as from the general mortality statistics of this and other countries, and from the mortality experience of the older life insurance companies.

The statistics of the autopsy room, and of the life insurance companies would seem to indicate that this increase is chiefly in the internal or visceral form of cancer, and, therefore, may be due, perhaps, in large measure to more accurate methods of diagnosis and classification. It would hardly be fair to infer from anything yet published, that there is any especial increase in cancers of the more superficial, and therefore more easily recognized parts of the body; as for example, the tongue, lip, breast or testicle. In any very marked general increase, it would seem as if these parts should share. Whether they do or not, would certainly appear to be important in reaching a conclusion on the larger question.

In spite of the efforts so long and earnestly devoted to the study of cancer in the laboratories of the world, its origin and nature still remain an impenetrable mystery. From the clinical side, it seems as if an infectious agent must be found, and it is believed that the agent will be found to be a protozoon such as is found in malaria, and is thought to have been found in smallpox and scarlet fever.

From the laboratory side, however, the discovery of such an organism, or of any organism, as the specific cause of cancer, seems highly improbable. Meanwhile we must go on empirically attempting its removal by radical operation, and waiting for its local or internal reappearance.

In my former paper, I said that I purposely avoided the use of the term cure, because it seems to be impossible to fix a limit beyond which it may not reappear, and I still think it much more exact to speak of immunity for a longer or shorter period, rather than of cure, and to omit all reference to a three-year limit.

It is perfectly true that recurrences are more common in the first year than in the second, and in the second, than in the third, and in the third than in the fourth, and so on progressively; but the progression is a regular one, with no more relative difference between the third and fourth years than between the second and third, or the fourth and fifth.

The use of the three-year period as the limit which divides the probability from the improbability of recurrence, should be abandoned, as it no longer has any foundation for its existence.

---

[1] Boston Med. and Surg. Jour., Aug. 30, 1900.

Since 1900 there have been no valuable additions or modifications of the technic of the radical operation as then described. At that time, it seemed as if the field of operation were likely to be extended. Halstead proposed to remove the glands from the lower cervical triangle in every case, and Cushing had essayed to follow the affected lymphatics down into the mediastinum. Neither of these plans has received much encouragement, and both seem likely to fall into disuse.

Whatever may be one's theory of the origin of cancer, all agree that it is disseminated through the lymphatics, and that the probability of its thorough extermination is inversely in proportion to the number of glands secondarily involved. The free anastomosis of the lymphatics of the neck makes it altogether probable that if they are already involved, a radical or complete removal of the disease is very unlikely, and the attempted removal of more than doubtful expediency. Our efforts would better be directed to securing an early recognition of the disease and more prompt removal, than to an extension of the field of operation in neglected cases beyond the probability of a successful result.

One of the curiosities of the subject has been the discussion, during the last few years, of oöphorectomy for the relief of inoperable cancer of the breast. It was first suggested and advocated by Beatson of Glasgow in 1896, and Boyd,[2] in 1900, reported the results of 54 cases; 19 patients received more or less benefit, and 34 little or none at all. In some cases the superficial disease had entirely disappeared, and cancerous ulcers had healed over. But the benefit seemed to be of short duration.

Abbe, of New York, reported one or two very strikingly successful results, but they were reported so soon after the operation, as to be of little value in determining their permanent success; and, on the whole, as was to be expected, the idea seems to have been one of those curious freaks that now and then appear in surgery and medicine, hold the stage for a little while, and are soon forgotten. It never had the slightest rational basis for existing at all.

The application of the *x*-rays to the treatment of cancer of the breast has received some attention during the past few years, but this, too, has failed to accomplish much beyond the occasional healing of superficial ulceration, and the general relief of pain. As a means of effecting a radical removal, it is much less reliable than the knife, and takes so long that its preliminary trial wastes valuable time, and lessens the chance of a successful operation.

We find success, therefore, just where we did five years ago, depending on the radical operation as advocated so earnestly in this country by Halstead, viz., the removal of the entire breast with a large amount of overlying skin, with the pectoral portion of the pectoralis major muscle, and the whole of the pectoralis minor, and with the thorough and complete dissection of the axillary space.

Further experience confirms the opinion expressed in the previous report, that removal of the muscles in no way interferes with the use of the arm. In this second series there has been much less impairment of usefulness than was encountered with the earlier operations, where the muscle was untouched. The removal is more thorough, and the dissection of the axilla, which in the present state of our knowledge is essential to a thorough operation, is made safer, easier, and far more complete.

SUMMARY OF CASES.

In the report of 1900, there were 46 cases, and of these, at the present time, 8 patients are living and well without recurrence. In 3 cases, 12 years have elapsed since the operation; in 1, over 11 years; in 1, 10 years; in 1, 9; in 1, 8; and in another, over 6 years. In the ninth case, the patient who was living and well at the time of the report, died 6 years after the operation of probable cancer of the brain, although no verification of the diagnosis could be made, as postmortem examination was refused.

There were no deaths from the operation, but local or regionary recurrences were noted at least in half of the cases. As many of these operations were done before I began to remove the pectoral muscles as a routine practice, now seven years ago, and were therefore less thoroughly done, I expressed my belief then, that the later results would be better, and I take pleasure now in presenting the record of what has been done from the beginning of 1899 to the end of 1903.

There are in all 62 cases, and here, as in the previous series, there has been no mortality from the operation, every one of the patients having recovered fully and completely, so as to be discharged from the attending physician's care; making 108 cases, without a single operative death. In all but 5 of these 62 cases, the muscles were removed as described above. In 3 of these 5, a palliative operation was done, as the disease had progressed so far that radical removal was impossible; and in 2, to which future reference will be made, only the tumor was excised. To those patients who were living at the time of the previous report, and to all in the present series of 62 cases, circular letters were sent requesting the following information:

Has there been any sign of return of the disease?
If so, when did it first appear?
If so where did it first appear?
Present condition.
If not living, date of death—cause of death.
Evidence of return of the disease, whether internal or external.
Name of physician attending at death.

Answers have been received from the patients, their attending physicians, or both, in every instance but one. In that case, the patient can not be traced. Deducting that one, the three incomplete palliative operations, and one case in which death was due to typhoid fever three months after the operation, and we have to consider 57 cases. In every one a pathologic examination and report has been made by Dr. F. H. Baker, and the clinical diagnosis of cancer has been confirmed. No attempt has been made to divide the growths into the so-called varieties of cancer, such as the medullary, schirrhus, adenocarcinomatous, carcinamatous, colloid, etc. Such a classification has always seemed to me very inexact; just how much fibrous stroma is necessary to make a growth schirrhus, how soft and cellular it must be to be classed as medullary, and so on, must depend entirely on the individual judgment of the examiner, and it would hardly be expected that any two classifications of a hundred specimens would be alike.

Of these 57 operations, 38 were done between 1899 and 1902; i. e., all of them more than three years ago. Fifteen of these patients, or 39.5 per cent, are alive and free from recurrence at the present time. In 2, more than 5 years have elapsed since the operation; in 8, more than 4 years; and in 5, more than 3 years. In the earlier series of 46, only 11 passed the 3-year limit free from recurrent disease; so that the results as regards immunity, are distinctly better in the later series, which comprises the more radical operations.

---

[2] Brit. Med. Jour., Oct., 1900.

If we turn to the unsuccessful cases, the improvement is much less marked; in the earlier series there were 23 patients in whom the disease reappeared locally, or 50 per cent.; in the later series there are 20 patients in whom local or regionary recurrence has been noted, or 53 per cent.; I group the local and regionary recurrences together because even when there is no appearance of disease in the external skin, an infiltration of the cervical or supraclavicular glands, and the hard, brawny swelling of the arm due to pressure on the axillary or subclavian vessels, are really evidences of a return of the cancerous disease in the track of our operation; and of quite a different character from the secondary growths which we observe in the stomach, liver, and brain, often after so long a period of immunity, as to encourage one to believe in the possibility of a permanent cure.

AGE OF PATIENTS.

A study of the ages of these patients at the time of operation throws little light on the value of age as a factor in determining the possibility of recurrence. Of the 88 patients thus far considered, 7 were between 30 and 40; 29 between 40 and 50; 22 between 50 and 60; 23 between 60 and 70; and 7 between 70 and 80. Of those who passed the 3-year limit without recurrence, 2 were between 30 and 40; 10 between 40 and 50; 5 between 50 and 60; 6 between 60 and 70; and 3 between 70 and 80. From these figures, it would appear that almost one-half of those between 70 and 80 had remained well; that about one-third of those between 30 and 50; and only one-fourth of those between 50 and 70, were equally fortunate.

This would seem to confirm the prevailing impression that cancer in very old people is less malignant than in the earlier years, just as all the vital processes are less active; but it is rather surprising to find that the patients between 30 and 50 have done a little better than those between 50 and 70. Of the two patients who were under 40 years of age—one was 34, and the other 38 years old, and both have been over 4 years without reappearance of the disease.

In both, microscopic examination showed that not only the breast, but the axillary glands were infiltrated with cancer at the time of the operation. It is unfair to draw any conclusions from so small a number of cases, but I think we may safely say that these results confirm the favorable prognosis generally accepted in patients over 70 years of age; and that they hold out greater hope than we have usually dared to express in the cases which appear before the climacteric.

DURATION OF DISEASE.

It is interesting to study the length of time which the disease is known to have existed prior to operation, but such statistics give little accurate information. It is very doubtful if any of these patients knew within many months of the time when bunches first appeared in the breast. How common it is to have a patient ask advice in regard to a lump in the breast, which she had discovered for the first time a week or two before, but which, from its size and feel, the surgeon knows must have been growing many weeks, if not months.

Perhaps, however, in a large enough series, the error would be so nearly constant, that one could at least be sure which were earlier, and which were later operations. In this present series of cases, there were 74 in which the duration of the disease is given; in 5, it was less than 3 months; and of these, 1 patient is alive and well 12 years after operation; in 18, it was between 3 and 6 months, and of these 5 patients are alive and well from 12 months to 3½ years later; in 20, it was from 6 to 12 months; and of these, 5 patients are free from recurrence from 13 months to 3½ years; in 22, it was from 12 to 24 months; of these 6 patients have had no return from 11 months to 3 years, after the operation; and in 9 cases the disease had existed over 2 years at the time of its removal; and 4 patients are still free from any signs of recurrence; 9, 5, 3¾ and 3 years respectively.

Certainly no deductions of any value can be drawn from these figures. The smallest percentage of those remaining well after the 3-year limit, is among those who were operated on earliest, and the best results obtained were among those in whom the disease had existed the longest; a striking illustration of the unreliability of figures.

I believe that each of these 4 patients in whom the disease had been present over 2 years, and who are still well, represents a less malignant form of cancer, or a personal resistance to cancerous invasion. We have not yet learned to differentiate between the degrees of malignancy, any more than we have discovered why some streptococcic invasions are so much more fatal than others. Until we can do this, I doubt if much of value is to be derived from the study of the duration of cancer before its removal.

TIME OF RECURRENCE.

Of more importance than the age of the patient, or the duration of the disease, are the statistics which show the time when recurrence of the disease was first noted, and whether it took place in the neighborhood of the scar of the previous operation, i. e., locally, or more remotely, in other parts of the body.

Halstead made another division, which he called the regionary recurrences, i. e., those in which the scar and adjacent skin were not involved, but in which the disease appeared in the cervical and infraclavicular glands. The distinction seems to me rather a fine one, and I have preferred to call everything local, which appears in the vicinity of the former operation, and presents visible or palpable signs of recurring cancer.

In the earlier series of cases, we find that local recurrence took place in less than 6 months in 11; in less than a year in 7; in less than 2 years in 5. Internal recurrence was noted in 8; in 5 of them within a year; 3 times it is stated that the disease appeared in the stomach, once in the lungs, and once in the "bowels"—in another case, the disease is said to have been noticed first, 2 years after the operation in the abdomen, and death followed a year later with no local manifestation. One patient died 3½ years after operation, with cancer of the clavicle, and generally disseminated visceral cancer; while the eighth died 6 years after operation of cancer of the brain.

It will be observed that local recurrence occurred 3 times oftener than internal, and that in more than three-fourths of the cases, it occurred within a year. Now, if we come to the second series of cases, we find that local recurrence was observed in 7 cases within 6 months; in 3, within one year; in 7, within 2 years; and in 3, within 3 years; while only 3 patients died from internal cancer without any local manifestation. Thus, only half of the patients had presented signs of local recurrence within the year. It will be noted, therefore, that not only has the number of those who have had immunity for 3 years increased in the second series, but the period of immunity in the rest has been decidedly longer.

I believe that this is the result of a more thorough and radical removal of the primary disease, and I am strengthened in this belief by a consideration of the patients who were operated on in 1902 and 1903, and which I have not included in these summaries.

In 1902, 11 patients were operated on for cancer of the breast; 7 of whom are still free from any signs of the disease; 2 died with reappearance of the disease locally within one year; and in 1, a local recurrence was removed in 1903, and she is still free from any further manifestations. Thus, in only 3 cases out of 11, has there been any recurrence of the disease locally, and all are 2 years old, and some of them lack but a few months of being 3 years old. One patient died within 3 months of cancer of the lung, which was probably present at the time of the operation, but not recognized.

In 1903 there were 9 operations, and in only 2, has there thus far been any recurrence. One was a patient who had been under the care of a "cancer doctor" for 4 months, and presented a sloughing ulcer, involving the whole breast; the glandular infiltration extended beyond the possibility of its complete removal, and she died with signs of local recurrence within 4 months.

The other was a very advanced case, in which I found enlarged glands reaching up above the clavicle, beyond the point where I could remove them, and therefore stated in my notes of the case that I considered recurrence merely a question of time. In one other case, in which the patient was operated on 2 years ago last May, there are some indications of malignant disease of the stomach, but this is not yet certain. In any event, here are 6 out of 9 patients who have lived beyond the year, 5 of them more than 2 years without any reappearance of cancer.

CONCLUSION.

Our investigations into the time when the recurrent cancer of the breast is likely to manifest itself, would, therefore, appear to show that a much longer period of immunity may be safely promised, now that the disease is more thoroughly and radically removed at the outset, than was formerly thought possible.

I think that these results fully justify the expression of confidence contained in my former report. No attempt has been made to select cases favorable for operation. No patients have been rejected except those in which it was perfectly evident that all the diseased area which could be seen or felt, could not possibly be removed; e. g., those cases in which the cancer was already firmly fixed to the chest wall, or in which the cervical and infraclavicular glands were so large as to be palpable.

Partial operations, such as these conditions make necessary, are doomed to failure from the start, and should not be attempted. Under all other circumstances, a radical removal may be safely advised. Even then, the disease on dissection will often be found to extend far beyond the limits which were recognized at the preliminary examination, but this chance must be taken, and even if the axillary glands are considered enlarged, if those beyond can not be felt, the patient should be given the benefit of as complete an excision as is possible.

As I stated in an earlier part of this paper, I prefer not to speak of any of these cases as cured. I am not at all sure yet that cancer is ever cured, in the sense that benign tumors are cured by their removal, but I do believe that more radical and improved methods of operating have lengthened very much the period of probable immunity from a recurrence of the growth, and that the limit of benefit has not yet been reached. I think the results of these later cases justify this belief.

REPAIR OF THE PERINEUM.*

GEORGE B. SOMERS, M.D.
SAN FRANCISCO.

If we examine the status of the operation for repair of the perineum, we find the following suggestive facts. In the various text-books and standard articles on the subject there are between 25 and 30 different methods described. Running through these we fail to find any common law or principle that governs them.

The word perineorrhaphy means simply sewing the perineum. If we were to depend on the study of these operations in order to find out whether it has any deeper meaning we should conclude that the word is used literally. That is to say, the majority of operations are simply methods of sewing and patching rents or tears.

Perineorraphy should imply the restoration of the function of the perineum by restoring the anatomic relation of its structures.

Before offering a practical method of repair, there are certain premises that should be accepted. They may be summed up as follows:

1. The usefulness of the perineum depends on the action of its muscles, rather than on its bulk or the strength of its fascia.
2. The chief functional structure of the perineum is the levator ani.
3. When the function of the perineum is at fault, it is the levator ani more than any other structure that needs repair.

The realization of the prime importance of the levator ani has apparently had very little influence on the technic of perineorraphy. I know of only two or three authors who insist on direct repair of this muscle and *who show how to do it.* By establishing its importance we realize the superiority of active function over mere bulk and acknowledge that the good perineum depends on what it can do rather than on how it looks.

It is difficult to disabuse ourselves of the idea that the function of the perineum is dependent on its size, or shape, or the strength of the tissues of which it is composed. In other words, we are prone to attribute to it passive strength, rather than active function.

The perineum is the meeting point of several muscles whose function it is to keep the rectum, vulva and vagina closed.

The rectum is closed by the powerful sphincter ani, but with this muscle we have nothing to do in the ordinary repair of the perineum. The muscles that concern us are the superficial perineal and the levator ani.

The vulva is kept closed by the superficial muscles.

---

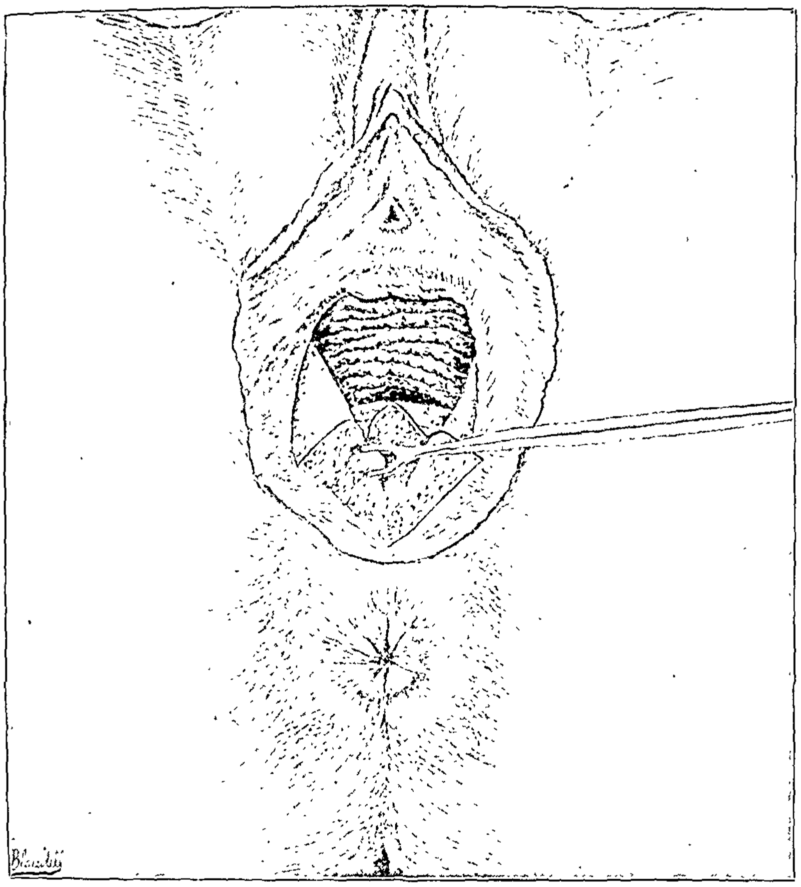

Fig. 1.—Edge of levator fished out.

Of these the bulbo-cavernosi keep the labia together, and narrow the vaginal outlet.

The transversus perinei assist in keeping the entrance closed and have some action in lifting the perineum as a whole, but neither of these muscles have much to do with keeping the vaginal walls in contact. In order to demonstrate this point we have only to call attention to the conditions found in a skin perineum where the bulbo-cavernosus and transverse perineal muscles may be intact and yet all the symptoms of relaxed vaginal outlet be present.

Suppose, however, we take the opposite condition of things, where the superficial muscles are injured but the levator ani remains unimpaired. Here we find that even where there is considerable gaping of the vulva the vaginal walls still remain in contact and no rectocele or cystocele occurs.

It is, then, the firm closing of the vagina, keeping the walls in contact and excluding the air, which prevents prolapse of the vaginal walls. That the levator is the chief factor in maintaining the closed condition may be shown first by testing with the examining finger, second by dissection, which reveals a considerable bundle of fibers running between the rectum and the vagina and which evidently act as a sphincter.

It follows from what has been said that as long as the levator is uninjured a laceration of the superficial muscles hardly needs repair. Suppose the vulva does gape a little and expose some of the vaginal mucosa, no harm is done, and we know from experience that nearly every woman who has borne children presents this condition. To repair in such a case is nothing more than cosmetic, and we are hardly justified in advocating cosmetic operations in this part of the body, at least in polite society.

On the other hand, when the perineum does not perform its duty, when there is rectocele or cystocele, then the levator ani is at fault. It is torn or stretched or relaxed, and its repair must be the chief aim of any operation designed to restore the perineum.

CONDITION OF THE LEVATOR WHEN INJURED.

In childbirth the levator ani is enormously stretched and sometimes lacerated. If injured, the ruptured ends retract, diminishing the thickness of the perineum in proportion to the injury to the muscle. The retracted ends may be found at the sides of the vagina. In place of a body, we have remaining between rectum and vagina only a thin septum consisting of rectal mucosa joined to vaginal mucosa. In some cases where there is not a complete laceration of the levator fibers, they are so relaxed or overstretched that they can not properly keep the vagina closed. The result is a hernia of the pelvic contents. If

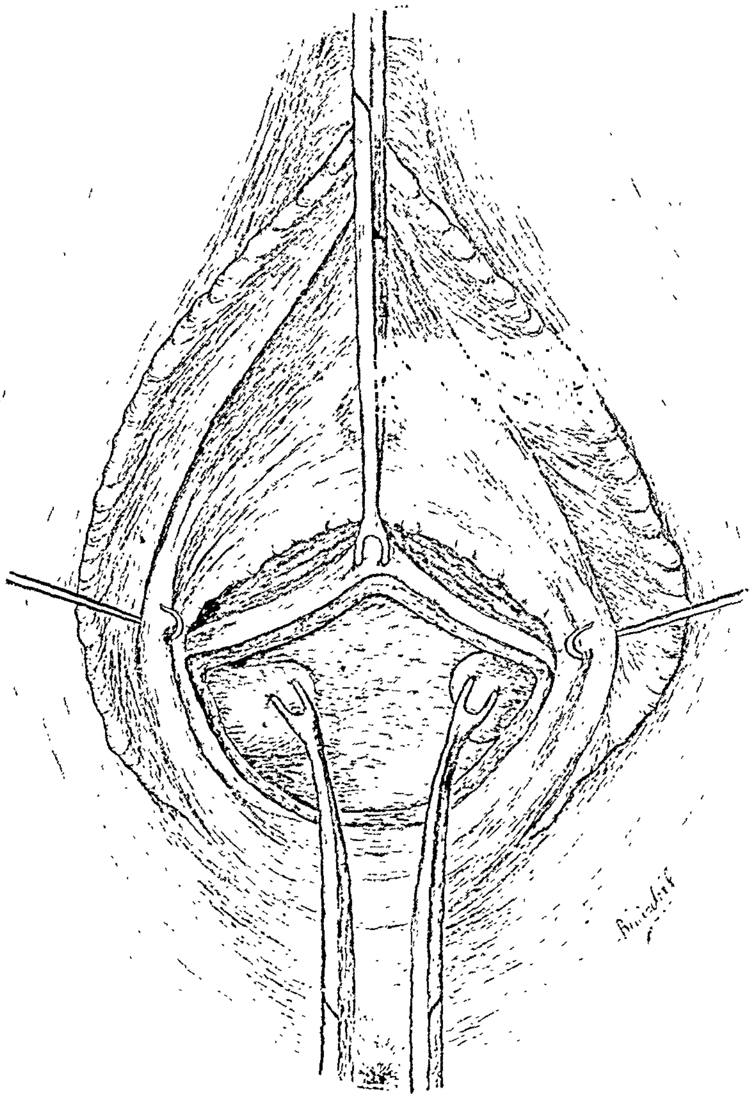

Fig. 2.—Both edges held ready for suturing.

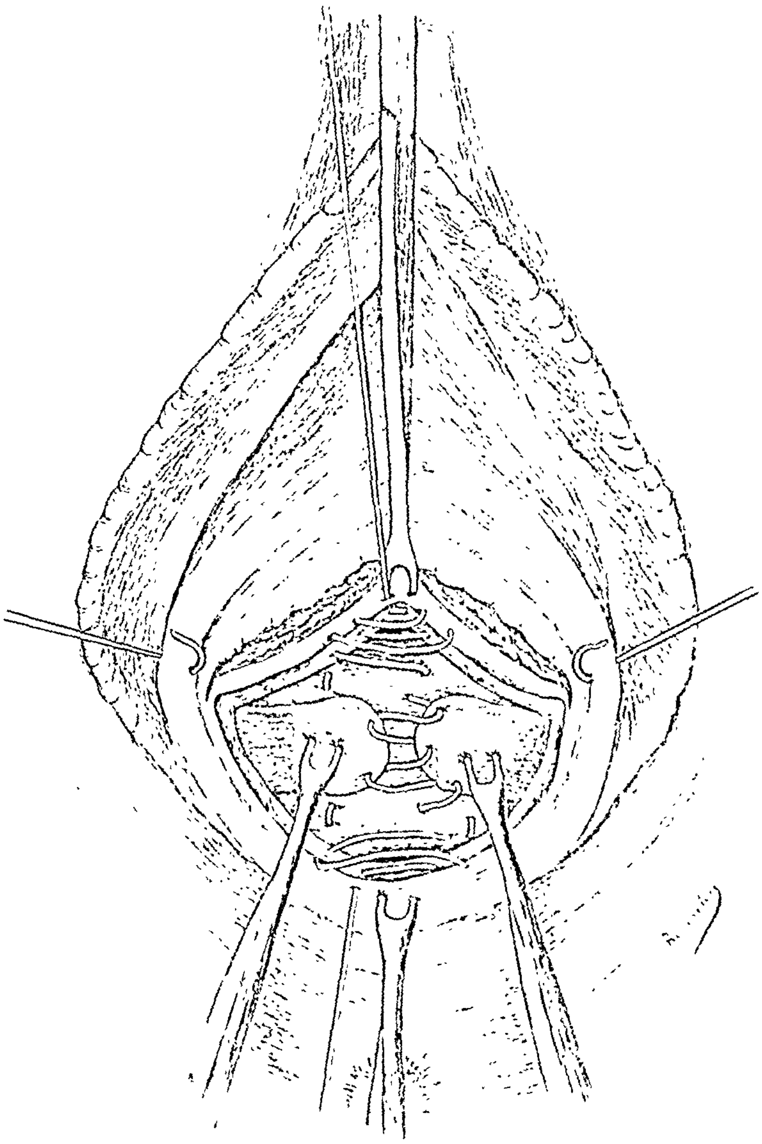

Fig. 3.—First suture inserted (vulsella should still be in place).

we could examine the injured levator ani, stripped of all other tissues, we would find that it practically presents one large opening for rectum and vagina, instead of a separate opening for each. Therefore, in order to cure the hernia, the openings through the pelvic floor must be made smaller by restoring to their former relations the retracted ends of the levator ani.

EMMETT OPERATION.

Do the ordinary operations bring the levator ani fibers directly in contact? In the Emmett operation, the inverted W denudation leaves a tongue in the median line, which is a portion of the original rectocele. This tongue is a thin septum consisting chiefly of vaginal mucosa joined to *rectal mucosa and either containing no* levator fibers, or at most fibers that are relaxed. It is, then, a pathologic structure and in no way suitable to form a connecting link between the retracted ends of the levator. Yet in the operation this intervening tongue of rectocele is sewed to the levator on each side. It serves to keep the divided ends apart rather than to unite them.

HEGAR OPERATION.

In the Hegar operation, the triangular denudation leaves nothing in the way of direct union of the fibers, but there is no special effort made to isolate, expose and unite them. As they are retracted, they are necessarily covered with more or less tissue. Simply to bring the denuded surfaces together does not bring the two portions of the levator in direct contact.

REED'S OPERATION.

One of the very few efforts to get the levator directly united is made by Reed. He splits up a flap, as in Tait's operation, feels for the levator with the finger, passes two sutures through each edge and in tying draws them together in the median line. The flap is then sewed down over the united muscle. To my mind, this operation is based on correct principles. Where there is but a small amount of redundant mucosa it is above criticism. In the majority of cases, however, it is desirable to remove more or less tissue on account of redundancy, the presence of cicatrices, irregular sulci, etc. Accordingly, the following technic is offered as an easy method of exposing and uniting the le-

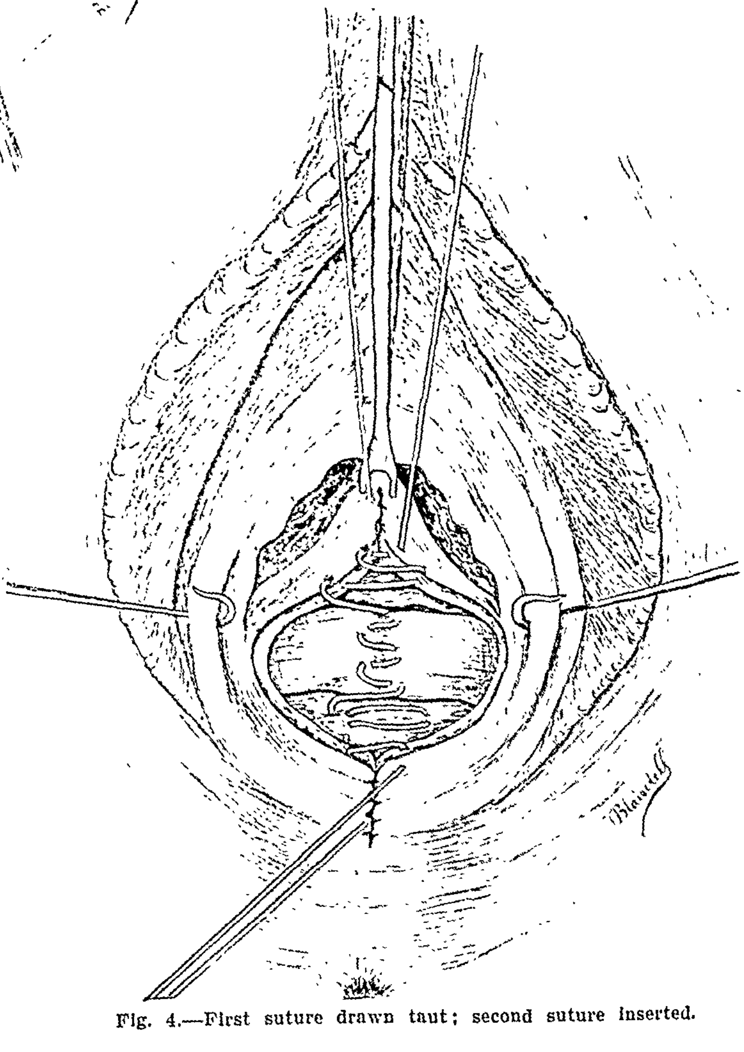

Fig. 4.—First suture drawn taut; second suture inserted.

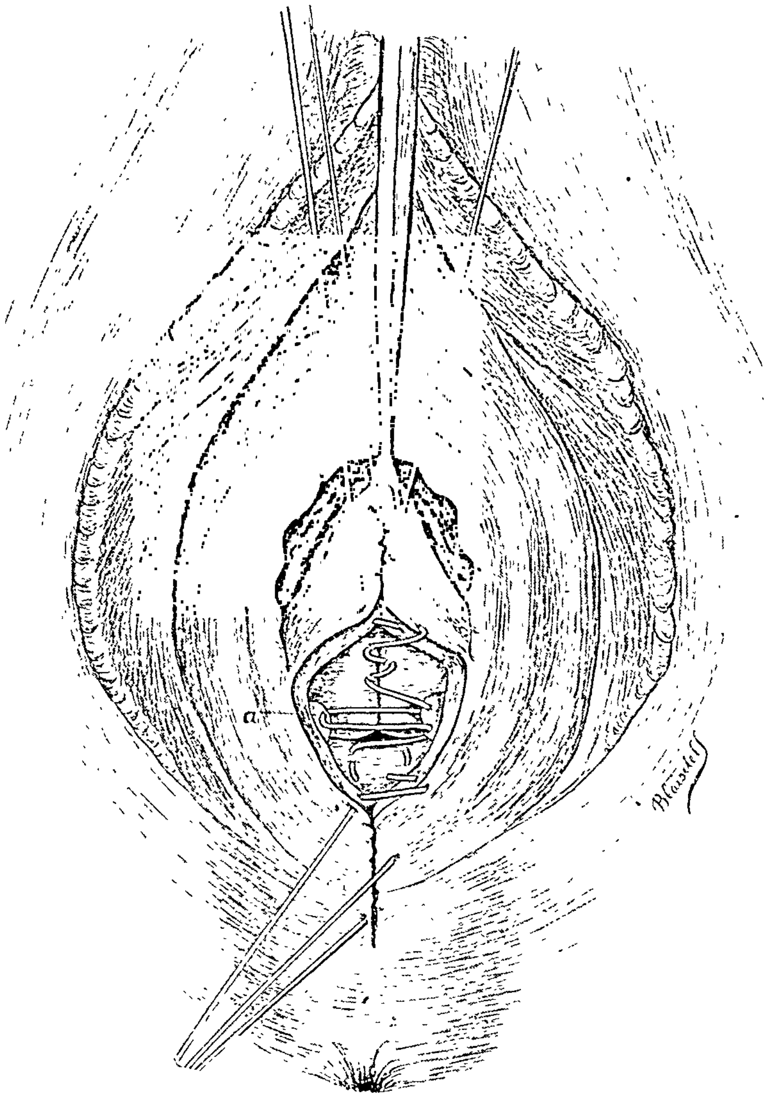

Fig. 5.—Second suture drawn taut; third suture inserted.

vator fibers, adapted to cases where there is much relaxation or deep sulci.

FISHING OPERATION.

In the first place, the edges of the levator are located on either side by examining with a finger in the vagina. A simple denudation is now made with the idea of uncovering the points where the muscle is felt. A triangular denudation answers as well as any, and is adopted because simple and convenient.

When the mucosa is removed, the muscle is again felt for, a vulsellum or tenaculum forceps is pressed into the tissues, the edges caught and fished out so as to be freed from the surrounding tissues (Fig. 1). The same is done on the opposite side. The two portions of the muscle are thus made to stand out prominently, are under perfect control and may be examined and united under guidance of the eye (Fig. 2).

It seems to me that some such exposure of the levator ani should be the basis of every operation for repair of the perineum, at least where there is relaxation or a rectocele. We can not but acknowledge that it is a rational procedure, provided we concede the paramount importance of the levator ani.

How the edges shall be brought together makes little difference and may be left to the choice of the operator, but the point insisted on is that, in some way, they be exposed and directly united.

THE SUTURE.

In considering how the parts may best be united, it develops that a great deal of trouble has been experienced with the suture. Probably more varieties of suture have been suggested for perineorraphy than for any other one operation. The reason for such a great variety is to be found in the common experience of operators. They find that the sutures fail to hold, or cut into the tissues, or produce stitch abscesses, or in some cases even bury themselves completely.

The difficulties are due partly to the impossibility of protecting the perineal region from rectal, bladder and vaginal discharges. But my own experience and study of the subject lead me to believe that failure is most frequently due to the use of interrupted sutures. Sutures that are tied necessarily interfere more or less with circulation. How can any tissue live that is packed with many closely set, tied sutures, as is recommended in many operations?

The unyielding nature of the interrupted suture is the most serious drawback to its use in perineal work, for any slight swelling causes it to cut into the tissues and open up avenues of infection.

Buried sutures in the perineum are always objectionable, because even in the hands of the most careful they may become infected and cause failure.

A suture inserted in the perineum ac-

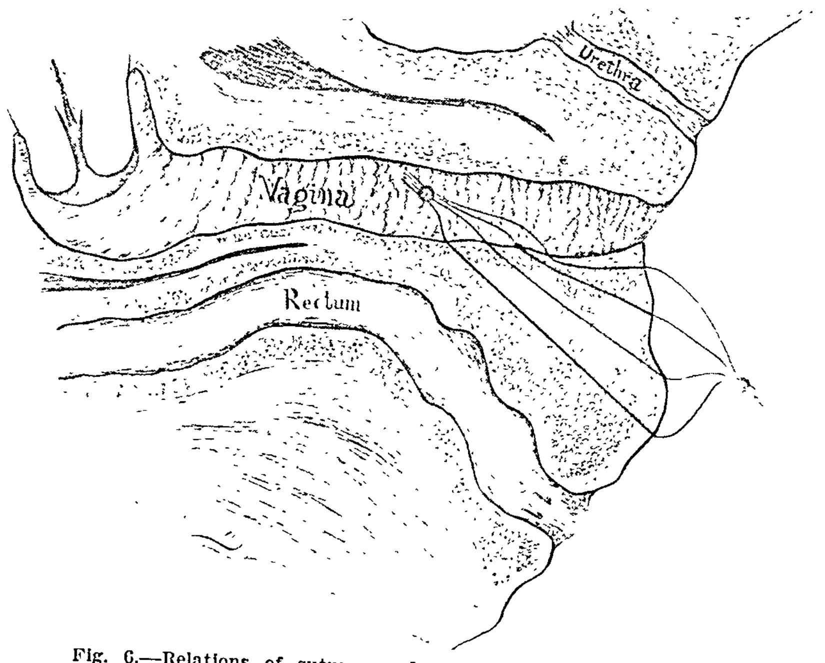

Fig. 6.—Relations of sutures and method of clamping.

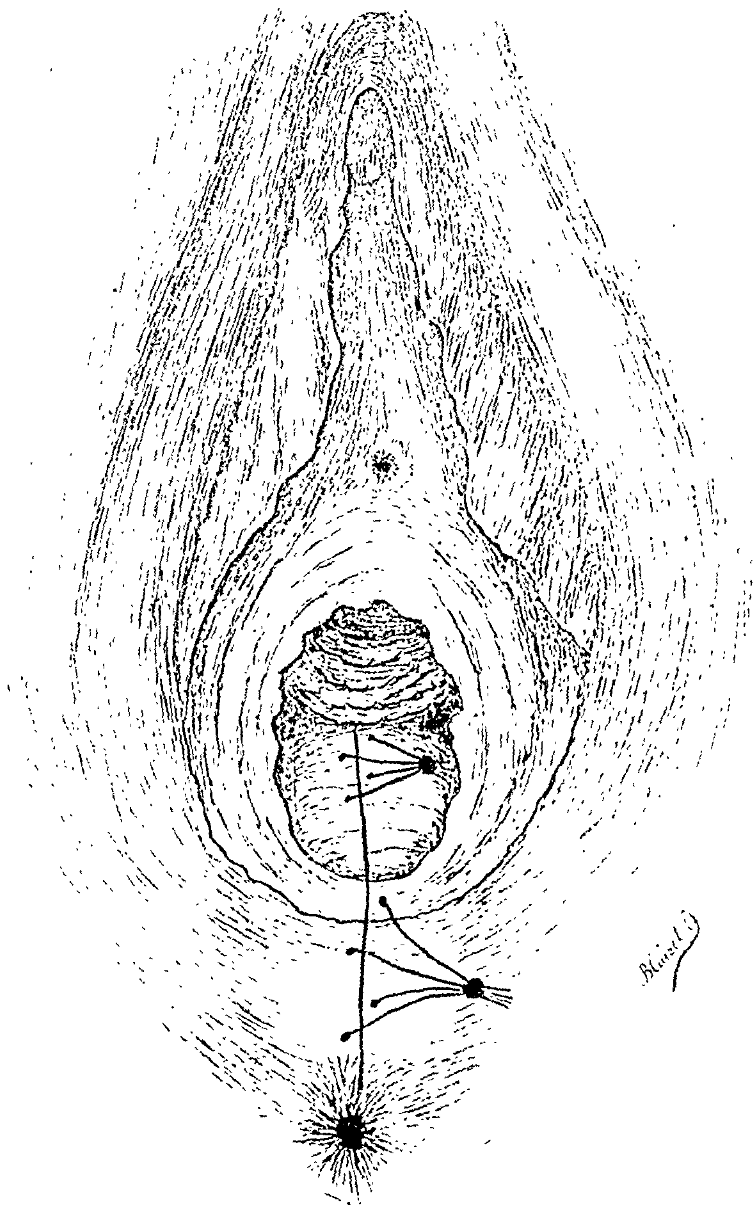

Fig. 7.—Operation completed.

cording to the following technic appears to obviate the chief objections to both the buried and the interrupted suture, and at the same time allows for swelling.

Silkworm gut is used. Passing through the apex of the triangular denudation (Fig. 3,) the suture is inserted with a mattress stitch, from side to side, in the deepest portion of the wound. In passing by the exposed levator ani fibers (still held by vulsella) it passes through the edges of each two or three times. It then continues in the deep portion of the wound, taking up next the tissue over the denuded ends of the superficial perineal muscles. Finally it emerges through the skin, on the perineal surface, just above the lower angle of the wound. It is then drawn taut approximating the tissues. A second and third are passed in similar fashion, each taking in a portion of the levator ani, one above the other (Figs. 4 and 5). As each suture is drawn taut, the tissues come together, bringing the denuded surfaces in contact.

The fourth suture is submucous and serves for a final closure of the wound. When all the sutures are inserted and drawn taut they have the relations shown in Fig. 6.

The most important feature of the suture is the method of fastening the ends. After making certain that the sutures are all drawn taut, the vaginal ends are gathered into a single shot and clamped from half an inch to an inch away from the surface. The perineal ends are then likewise clamped about the same distance from the surface.

This device allows for swelling. While the sutures keep the parts firmly in contact, yet if any swelling occurs the tissues simply slide along the free ends toward the shot, taking up more or less of the slack.

The appearance of the parts when the operation is finished is shown in Figure 7.

In removing the sutures, which is usually done on the tenth day, the shot within the vagina is seized and the sutures cut off close to the surface. The perineal ends are then grasped and pulled out.

By this method of suturing the perineum is built up layer by layer and the surfaces approximated evenly, without tension and without constriction of the circulation. The consequence is that the tissues are in the best possible condition for immediate union.

In case swelling occurs, the sutures can not injure the tissues by cutting into them or cutting out. The surfaces are still kept in contact against the time when subsidence of the swelling or inflammation permits the healing to proceed.

606 Sutter Street.

DISCUSSION.

Dr. J. H. Carstens, Detroit, said that the pelvic organs are not supported by muscle. Muscle never supports anything. *It is the fascia, the tissue between the muscles.* Muscles simply stretch out and they get shorter, but they can not hold anything by themselves; and so it is with the uterus. It is the pelvic fascia, the fascia between these various layers of muscle that make the perineum strong. Dr. Somers talked as though the tear is always in the center of the perineum. That is the case only occasionally. The perineum tears all over, in all directions, according to the strength of the muscle. The tear is ragged and depends on the position of the presenting part. All these things have to be borne in mind. There is *no one* correct way of repairing a torn perineum. It depends on the individual case. Sometimes one must put in the sutures one way and sometimes another. To restore a torn perineum the surgeon must be an artist. In operating immediately after delivery, before the muscles have had a chance to retract, with a large *en masse* suture one may be able to bring the muscles together pretty fairly. But this can not be done after the muscles have retracted. If the ends are pulled together, the probability is that they will not be in perfect apposition with each other. If the tear is on one side and ragged, this method will fail utterly. Dr. Carstens declared that a catgut ligature can not be inserted as Dr. Somers described, and challenged anyone to do it. The suture straightens out and then cuts through the tissues. All silkworm-gut ligatures, no matter how they are put in, will get round. Dr. Carstens criticised the big flap made by Dr. Somers, and said that it stretches and contracts, and if the woman becomes pregnant again there is not enough elastic tissue to stretch out and the perineum is bound to tear again. The surgeon has no more business to remove any of the mucous membrane and submucous elastic tissue in a vaginal operation than in a hare-lip operation. The flap-splitting operation of Tait is good, but it is too much like butchery. That was one of Tait's distinctive characteristics; he lacked the delicacy of touch that a gynecologist should have. He put in a big *en masse* stitch with a big needle that looked like a poinard, and then he wondered why the woman had pain after the operation. One can perform a delicate flap-splitting operation, sometimes going nearer to the vagina and sometimes nearer to the rectum. In performing this operation, the flap is dissected out and lifted up two inches or two and a half inches, so as to get beyond the scar tissues. That gives a big opening. If the rectal muscle is torn, it is drawn together with dry sterilized catgut. Then the perineal muscles are sewn together separately, the fascia is brought forward together with the muscle on either side, little sutures are put in or run together with a little needle, bringing together one muscle after the other, and, finally, when the tissues are in contact, then, with a running stitch of fine catgut, the skin is brought together, and the whole structure is restored, muscle to muscle and fascia to fascia. There is no cutting or giving way of sutures and the woman has no pain. There is no tension on the sutures, no tearing out of sutures.

Dr. H. O. Marcy, Boston, said that the repair of the perineum seems to be the *bete noire* of obstretric surgery. All gynecologists certainly should agree on the general principles of the operation, though even these do not seem to be well recognized. He said that all must agree with Dr. Carstens regarding the importance of the fascia as well as of the muscles. The site of the rupture will necessarily vary, as the direction of the force is not uniform. The pelvic floor in both sexes is made up of muscles and fascia blended together and wrapped and reinforced by connective tissue. When these tissues are torn asunder they must be restored as nearly as possible to their former condition. In order to reunite the separated transversi, the vagina must be separated from the rectum. This separation should be carried to the crest of the rectocele by a free open dissection. It is done best by dilating the sphincter ani and keeping the parts tense with the fingers in the rectum until the operation is finished. In this way the muscles are easily brought into view, and Dr. Marcy thinks that they are best reunited by a double continuous suture of kangaroo tendon, applied by means of a needle with an eye near the point, which is especially designed for this purpose. A shoemaker's stitch coapts and does not constrict the parts. A light running absorbable suture coapts the superficial tissues, building up the perineum to its normal depth. The skin is evenly joined on the median line and the line of suture is covered by a few fibers of absorbent cotton, wet with contractile iodoform collodion. This makes an effective antiseptic scab. With proper care, primary union will result. Recently a surgeon saw Dr. Marcy operate, and asked the matron of the hospital how many failures Dr. Marcy had in his operations, and he was told that not one failure had occurred in seventeen years.

Dr. W. F. B. Wakefield, San Francisco, declared himself thoroughly in accord with Dr. Somers, and with Dr. Carstens, whom, he thinks, has entirely misunderstood Dr. Somers. The only difference Dr. Wakefield can see in their technical construction is that Dr. Somers removes more mucous membrane than Dr. Carstens does. Dr. Wakefield has used Dr. Somers' method many times, with excellent results. He thinks Dr. Carstens' method will produce equally good results.

Dr. E. D. Ferguson, Troy, N. Y., said gynecologists must not lose sight of the fact that both muscle and fascia are essential to the perineum and pelvic floor. Dr. Carstens spoke of the inadequacy of the muscle, but there is the same inadequacy of the fascia. Both these structures must be brought together by interrupted or other sutures. The fascial tissues, if subjected to continuous pulling, will stretch. No muscle will stand continuous traction. It has a voluntary function. The result is that if one depends on fascia, it will elongate. If one depends on muscle alone, it will lose its power; but the muscle can contract and rest the fascia, and a long-continued traction will not produce a permanent loss of function if muscle and fascia can take each other's place.

Dr. Charles S. Bacon, Chicago, said that some years ago little was said about repair of the levator ani muscle, only about repair of the perineum. That, of course, is a mistake, and may lead to some errors in the consideration of this question. The levator ani muscle is extremely important, but a very essential part is also the muscle of the urogenital trigone. Between the fasciæ of this structure there is muscular tissue which has been divided into different layers. This muscle closes up that part of the pelvic outlet which is not closed by the levator ani, and through it pass the vaginal and urethral tubes. This must be considered in the repair of the lacerations of labor. Dr. Bacon stated that the structure of the urogenital trigone is very thick, and in a repair it must be brought together very carefully, and it occurred to him that it would not be repaired so well by Dr. Somers' method. The direction of the fibers is quite different from that of the fibers of the levator ani muscle; so that even if the method is a good one for the repair of the levator ani, it might fail to bring together the urogenital trigone structures. One would also suppose that this longitudinal suture would not bring together well the levator ani and its fascia. That, however, is a matter to be determined only by experience. One thing that should be emphasized, Dr. Bacon said, is the mistake that Dr. Carstens made in saying that the essential thing is the fascia and not the muscle fiber. Undoubtedly, the fascia is important, and one can not unite the muscle without bringing the fascia together, but to claim that the fascia is all-important is certainly a mistake. Fascia will not hold unless there is muscle. It is only the muscle of the natural ligaments of the uterus that holds. The fascia alone will not hold in the repair of the abdominal incision. The muscles must be united. Muscle tissue everywhere is of extreme importance for obtaining permanent results, and fascia is only the support of the muscle. While he agreed with Dr. Carstens in his technic, Dr. Bacon thinks it is a mistake to claim that the fascia is all-important.

Dr. F. T. Andrews, Chicago, said that while Dr. Somers has described a very beautiful operation for the repair of the perineum, a perineum is not worth anything unless it is in the right place. The levator ani muscle with its fascia is the thing to which attention must be given, but this muscle, after a laceration, has one large opening in it. The baby's head has come down through the pelvis. There are no tissues, practically, in the pelvis. The coccyx is crowded back. The anus is two inches below the coccyx and fully as far back, and the tissues are all crowded outside. The muscle and its fascia are no longer perfect. That has not all happened at once; there has been a long-continued pounding and stretching of the tissues. If that perineum is repaired by picking up the ends of the muscle and fascia and bringing them together, there is no longer a shallow bowl, but a deep funnel. The tissues have not been lifted so as to support the organs within. One can not accomplish the desired result by bringing the tissues together; they must be denuded in order to get down to the muscle and fascia and to put in the stitches so that every stitch draws the tissues forward. By measuring from the pubes, it will be found that the rectum is too far back; so, too, the vagina. The stitches should be passed so as to carry everything upward and forward. The laceration should be so repaired that there will be sufficient obliquity in the vaginal axis. To do this, the traction of all stitches should be upward and forward, thus restoring to the levator ani muscle its original shape, that of a shallow bowl.

Dr. A. R. Kiefer, St. Louis, believes that the reason operators differ in this matter is that there does not seem to be sufficient knowledge of the normal anatomy of the perineum. Much has been said about bringing the fibers of the levator ani muscle together. Normally, there is very little interlacing of the fibers of this muscle until it gets back to the rectum. Therefore, in an ordinary laceration of the perineum, very few fibers of the levator ani are torn. These muscles are held in close relation by the intervention of fasciæ, as mentioned by Dr. Carstens. These accurate descriptions of replacing the levator ani muscle fibers in the median line are amiss. Dr. Kiefer agreed that the thing to do is to try to replace the parts just as they were before the injury; therefore, there can be no uniform manner of denudation or of placing the sutures, because there is no uniform manner of laceration. He finds that sometimes he can use large stitches to advantage, and sometimes small ones. If, however, one introduces the large suture, beginning on the surface and picking up only the superficial portions of the denuded surface, it will result in a small area of included tissue which pulls the skin inward, and there will be a small perineum.

Dr. G. B. Somers declared it seems that we are still at sea as to what is really necessary to be done in repairing a lacerated perineum. The anatomy and function of the perineum are not understood. He does not maintain that one operation is better than another, but he does maintain that before repairing a perineum we must establish certain definite principles as a working basis; we must have an anatomic rather than a pathologic basis. One can build up a perineum by any one of about forty methods so as to get a good looking perineum, but the point is: Will that perineum last? With the Emmet or Hegar or Tait operation he has found that after six or eight months the tissues have stretched, because pathologic and not normal structures have been used. The first point he tried to demonstrate was the importance of the levator ani muscle. It is the most important muscle of the perineum, and unless the surgeon is convinced of that the operation is a useless one. The sphincter action of this muscle must be restored so as to maintain the closure of the vaginal walls, keeping the anterior wall in contact with the posterior. Dr. Somers expected to be misunderstood in many of the points he tried to make, and he expected that some one would bring up the old point of the difference between the muscle and the fascia. This shows that there is a lingering idea that the function of the perineum depends on the strength of the tissue of which it is composed, rather than on its sphincter-like action. No muscle is of value apart from its fascia, so that when in speaking of a muscle, one must also consider its fascia. The levator ani has rectal as well as vesical fascia, and both are important. It is true that tears rarely occur in the median line, and Dr. Somers' demonstration was as to the ultimate results of a tear in one of the sulci. The majority of lacerations occur in the sulci. He maintains, however, that the fibers gradually retract and atrophy, so that ultimately the conditions are the same as if the tear had been in the median line. With reference to the importance of the superficial muscles, he said that in the majority of women who have borne children, these are torn and the vulva gapes open, exposing more or less the entrance to the vagina, but a little farther within it is perfectly plain that the vaginal walls are held together by a strong band of levator fibers, and as long as these are intact there is neither rectocele nor cystocele. If one believes that the levator ani muscle is the principal portion of the perineum, and that the function of this muscle should be restored, then he must have some way of uniting it. Simply to use the Hegar or Emmett operation does not provide for a direct union of the two edges of the muscle. Dr. Somers' chief object in presenting the paper was to show an easy method of restoring the function of this muscle.

TYPHOID FEVER IN CHILDREN.*

WILLIAM J. BUTLER.
CHICAGO.

REVIEW OF LITERATURE.

The symptom-complex of typhoid fever seems to have been recognized by the earliest observers; not, however, under its present name, but by a number of different ones, derived from various characteristics of the disease, viz., from the character of the fever and its duration, from the predominance of nervous or intestinal symptoms, from septic manifestations, from its resemblance to other fevers, from its mode of prevalence, and from its supposed origin.

Hippocrates'[1] description of a fever observed by him would form an excellent clinical picture of what we now term typhoid fever

From Spigelius, in the seventeenth century, to the present time, various writers have described a disease which, clinically and pathologically, resembled typhoid fever.

FREQUENCY OF TYPHOID IN CHILDREN.

The occurrence of typhoid in children appears to have been an early observation. It seems quite impractical, however, to arrive at any accurate estimate of its comparative frequency for many reasons, unless we refer to statistics obtained in epidemics taking place in small towns. The following statistics may prove of interest in this direction:

Franque found in Nassua, in 31 years, among 11,028 cases of typhoid, 2,021 under 10 years. Gaultier de Claubery[2] found 31 per cent. under 15 years, out of 7,348 cases. Baginsky,[3] in 50 cases in a local epidemic, reported 16 under 10 years. Rosenthal, in a village epidemic, observed 28 under 10 years in 115 cases. Schadler,[4] under similar conditions, found 11 under 10 years, out of 144 cases. Murchison[5] reported 28.5 per cent. of 5,911 cases under 15 years. Curschman[6] reports 27.7 per cent. of his Leipsic cases occurring in children, and 11 per cent. of his Hamburg cases.

The above data does not admit of any accurate deductions as to its comparative frequency, except possibly the statistics of Rosenthal, Baginsky and Schadler, based on observations in localized epidemics. But even under the circumstances it is probably not infrequently overlooked in sucklings.

While typhoid in children is far more frequent in later periods of childhood, its occurrence in the earliest months, and even *in utero*, was early recognized, as indicated by the reports of Abercrombie, Charcellay, Mazzini, etc.

Innumerable reports have since appeared, which certainly represent but a small fraction of cases that have actually occurred. The fact remains, however, that it is comparatively infrequent when compared with later periods of childhood.

Wünderlich[7] states that it was seldom found in infants. but increased in frequency in children from 2 to 6 years of age, reaching its maximum for childhood in the latter year.

Montmollin[8] reported the greatest frequency from 6 to 12 years.

Table 1 gives more recent data quoted by Curschman[6] from Oldenburg Children's Hospital of St. Petersburg, from 3,504 cases of typhoid in children.

TABLE 1.—Typhoid Cases in Children's Hospital, St. Petersburg.

Between 1 and 6 months	.26	per cent.
Between 6 and 12 months.	.99	per cent.
Between 1 and 2 years..	4.94	per cent.
Between 2 and 5 years	42.3	per cent.
Over 5 years	51.3	per cent.

INFLUENCE FORMERLY ATTRIBUTED TO SEX.

Some of the earlier pediatricians attributed to sex a considerable influence in the predisposition to typhoid, as instanced by the following statistics:

Taupin reported 121 cases, of which 86 were boys and 35 girls. Rilliet and Barthez reported 111 cases, of which 80 were boys and 35 girls. Löschner,[8] in 104 cases, reported 62 boys and 42 girls. Friedrich, in 275 cases, 149 boys and 126 girls. Friedleben,[9] on the other hand, found greater frequency in girls; in 98 cases there were 46 males and 52 females. Murchison considered that the predominance of one sex in different hospitals is determined by accidental circumstances.

Baginsky[10] states that, in general, boys are more frequently attacked than girls. Curschman writes that both sexes are attacked with equal frequency.

Of my 210 cases, 106 were males and 104 females.

THEORIES OF CAUSATION.

It is quite interesting to note that of the earlier writers on the subject some believed typhoid contagious, while others took an opposite view. They called attention to its development in people recently arriving in localities where the fever was endemic. In Germany many referred it to poor hygienic conditions, foul air, damp, dark dwellings, and impure and improper food. At the same time they doubted its contagiousness.

In the first half of the last century, von Gietl,[11] of Munich, taught that it was disseminated by the feces of typhoid patients. Piedvache[12] (1849) came to the conclusion that, under certain circumstances, it was contagious. His chief argument was that, when one individual was attacked, many other cases often followed in the same house or district. Bühl[13] and Pettenkoffer[14] originated and advocated the ground-soil theory. Taylor,[15] in 1858, in England, reported an epidemic caused by cow's milk. Murchison advocated the theory of its dissemination by air and water polluted with decomposing sewage and other forms of putrefying animal matter.

Budd[16] believed the typhoid poison a specific agent, which, instead of developing, according to Murchison's theory, outside the body, was discharged with the stools. It, therefore, could not occur without the existence of a previous case. He further stated that if the specific poison in the stools could be destroyed the spread of the disease would be checked.

Gerhard, some years later, wrote that, while man does not possess a microscopic recognition or reagent for typhoid poison, if water contains more than a trace of ammonia and organic constituents, or more than four parts out of a million of saltpeter, it must be regarded as unfit for use and a capable vehicle of infective material. He considered the fever contagious in so far as long and constant contact with typhoid patients results in the transfer of the disease. Gerhard was also of the opinion that it could be transferred *in utero* by a healthy mother, analogous to variola, on the basis of cases reported by Schadler and Herard.[17]

It would seem that all that was lacking in Budd's theory, as suggested by Curschman, was the discovery of the bacillus, which occurred in 1880, being found by Eberth[18] in the intestinal lesions and spleen. It was later isolated by Gaffky,[19] and its morphology and cultural properties thoroughly described. Since then an enormous mass of literature has accumulated in the study of the bacillus which has brought forth many points of value, among others its occurrence in the stools, the comparatively frequent presence of the bacillus in the urine of typhoid patients, determining the infectious character of the excreta and the necessity of disinfecting the same.

Although much has been written on the tenacity of the typhoid bacillus outside the body under dry and moist conditions, and the possibility of its conveyance to the individual in dust, it is highly probable that practically all cases occur either by direct accidental conveyance from typhoid patient to those in immediate contact, through hands or articles being brought to or into mouth, when soiled by discharges of patient, or, which is by all odds the most frequent, the contamination of water or food by the typhoid bacillus.

The discovery of the agglutinating power (Widal[20] reaction) of the blood of typhoid patients or immunes on the bacillus itself has proved invaluable as a diagnostic resource, and likewise the isolation of the bacillus from the blood.

PATHOLOGY.

Taupin[21] and Rilliet[22] were the first to give special study to the anatomic changes in typhoid in children, with the view of determining any difference that might exist between those found in childhood and adult life.

Rilliet came to the following conclusions, among others:

"1. In children are found the lesions of Peyer's patches, the solitary follicles and mesenteric glands, such as are noted in the adult, but the ulcerations are smaller, fewer in number and more superficial. 2. Ulceration is not necessarily the result of phlegmasia, as it may end in resolution. 3. Cicatrization takes place rapidly. 4. Ulcerations of mucous membranes elsewhere are rare."

Gerhard stated that the changes in the bowel in childhood could deviate essentially in their development and extent from those found in adults. He believed, with Rilliet and Friedrich, that ulceration seldom took place between the second and seventh years, although occasionally found in sucklings. When ulceration did occur, the ulcers were few in number, but sometimes deep, even to the extent of perforation.

It was the general opinion of the earlier writers that the intestinal lesions were not numerous; that, as a rule, absorption of the hyperplasia, without proceeding to ulceration, occurred; that when ulcerations took place they were fewer in number, of slight extent and usually superficial, rarely progressing to the extent of perforation. As a result, local complications depending on the ulceration of the intestinal lesion were rare, as hemorrhage and perforation. Montmollin, on the other hand, reported ulceration in 77 per cent. of 23 cases in which autopsy was performed.

The enlargement of the mesenteric glands adjacent to the intestinal lesions presented no deviation to those found in the adult.

Barthez and Rilliet[23] found the spleen of normal size in about one-third of their postmortem cases. Barrier, Löschner, Friedleben and Bednar[24] reported it invariably enlarged. Gerhard wrote that the enlargement of the spleen can fail. The cause of this may be early death, or it may be the result of hemorrhage.

The liver is frequently enlarged and usually pale in color, turbid on section, and showing microscopically granular and fatty degeneration.

Respiratory Organs.—Laryngeal ulcers are rare, except in late childhood. They occur on the posterior wall at the insertion of the vocal cords, on the aryepiglottidean folds, and at the base of the epiglottis. A varying grade of bronchitis is common. Atelectasis is relatively frequently observed, resulting from severe bronchitis; occasionally hepatized patches, in some instances involving a whole lobe, are found. Hypostasis is rare, on account of the shorter course of the disease, as a rule. Taupin reported hemorrhagic infarct and gangrene of lung. Rupture of lung abscess into pleural cavity was reported by Löschner.

Kidneys.—The kidneys may show cloudy swelling with granular degeneration of the cells of the convoluted tubules. Seldom a nephritis develops. Rarely miliary abscesses of the kidney, or diphtheritic inflammation of the pelvis of kidney.

Heart.—Endocarditis and pericarditis are very uncommon. Of comparative frequency is myocarditis, which Rhomberg[25] reported existed in about 50 per cent. of all cases which came to autopsy. Endarteritis with gangrene are narrated by Trousseau,[26] in Baudelocque's and Patry's cases, one in a child of 10 years, the other in one of 12.

Nervous System.—Actual meningitis has been reported, and from the exudate which may be serous or purulent the typhoid bacilli have been recovered. Parenchymatous changes may be found in the peripheral nerves. The muscles often show the waxy degeneration of Zenker, and this is most frequently found in recti abdominis, adductors of thigh and pectoralis.

SYMPTOMATOLOGY.

In 210 cases here reported the children presented symptoms for some time, varying from a few days to ten days, before coming under observation. The average period was seven days. The symptoms noted during this time were as follows: In very young children, restlessness and irritability were frequently present at first. In many, however, there was drowsiness, with tendency to sleep a great deal. In older children, drowsiness, weariness, sometimes irritability, restless sleep, dizziness and buzzing in ears were noted. Headache was complained of in the majority of children old enough to localize pain, being present in 151 cases. Delirium was observed in several cases during this period.

Vomiting had occurred in 57 cases, in some once or twice at most; in others several times. In two cases it was more or less constant throughout the disease, both terminating fatally. Many of the earlier observers considered vomiting at the onset, especially when associated with constipation, as an unfavorable symptom, pointing toward a severe course.

With the beginning of temperature, thirst was invariably increased, and anorexia appeared.

Colic was complained of in 47 cases. In many of these the pain was more or less constant, and localized at the umbilicus or in the right ileocecal region. Other children with diarrhea complained of pain just before evacuations only. Colic seldom continued beyond the middle of the first week. In many a sensitiveness to palpation in the right ileocecal region persisted throughout.

Of 107 patients in whom the condition of the bowels was ascertainable, 69 had diarrhea, 31 constipation, and 7 were irregular. Chilliness was occasionally observed at onset, a history of chills being obtainable in 31 cases only. Friedrich noted chills in 6 of 83 cases.

Epistaxis does not appear to be so frequent during the onset in children as in the adult, it being found in only 29 of the 210 cases.

A slight angina was present in 3 cases; opisthotonos in 4 cases, and strabismus occurred early in 1 case.

SYMPTOMS AND SIGNS OBSERVED DURING THE COURSE OF THE DISEASE.

Anorexia was invariably present.

The tongue usually presented a whitish fur, with clean borders and tips, later becoming grayish or yellowish-brown and dry. In the severe cases, crusts appeared on the lips; the mucosa of the mouth looked swollen and turgid and bled easily. Sordes formed on the teeth if not cared for. A mercurial stomatitis occurred in one patient who was receiving calomel. A gangrenous stomatitis or noma was not found in any case. Extension of infection along the Eustachian tube, with resulting otitis media, was not uncommon, accompanied by more or less impairment of hearing.

Vomiting occurred in 28 cases during the course of the disease. In 13 of these it had been present at the onset. While vomiting at the onset would not seem necessarily to indicate a severe attack, its occurrence during the course of the disease seems to be of considerable significance, as suggested by the following case reports:

Case 143.—The patient vomited occasionally, had hemorrhages on the thirtieth and thirty-fourth days, and died in collapse eight days later.

Case 101.—The child vomited on the tenth and thirteenth days. On the fourteenth day perforation occurred, the patient dying two days later.

Case 159.—The child vomited on the seventeenth day; on the nineteenth day peritonitis developed. On the twenty-third day there was a copious hemorrhage and the child died the same day.

Case 4.—The child vomited the day before the hemorrhage The case terminated in recovery.

Case 39.—The child vomited on the fourteenth day and had a hemorrhage the same day.

In two cases in which vomiting was an initial symptom, the patients continued to vomit throughout, both dying, one in the first week, the other in the second. While vomiting occasionally resulted from administration of expectorants or as result of transient disturbance of the stomach, in many cases it seemed to antedate a serious complication.

Condition of Bowels.—The bowels in 184 patients, in whom this point was accurately noted, were constipated in 100 cases, and in 84 there was diarrhea. The stools in the young children were thin, yellowish-green in color, and sometimes slimy and curded. In older children they were of the characteristic pea-soup variety. Rilliet looked on constipation at onset as of serious prognostic significance. In the fatal ones of the 210 cases, the condition of the bowels is shown in Table 2.

TABLE 2.—Condition of Bowels in the Fatal Cases in the Series of 210.

	At onset.	During course.
1.	Constipation.	Constipation.
2.	Constipation.	Diarrhea.
3.	Constipation.	Diarrhea.
4.	Constipation.	Diarrhea.
5.	Regular.	Constipation.
6.	Constipation.	Diarrhea.
7.	Constipation.	Constipation.
8.	Diarrhea.	Diarrhea.
9.	Constipation.	Diarrhea.
10.	Constipation.	Diarrhea.
11.	Constipation.	Diarrhea.

While constipation was present in 9 of the 11 fatal cases at the onset, it can hardly be considered of special prognostic significance, as many cases of constipation run a mild course, and, *vice versa*, many cases beginning with diarrhea run a severe course.

---

[25] Rhomberg: Deutsches Arch. f. k. Med., 1891.

[26] Trousseau: Clinical Med., vol. ii

Abdominal pain, though not infrequent at the onset, is seldom complained of after the first week, except in cases developing complication.

Tenderness in the ileocecal region and gurgling are often found. Seldom, however, is the tenderness severe. Exquisite tenderness usually points toward involvement of the peritoneum.

Tympany of varying degree was present in most of the cases after the first week, in some forming quite an annoying symptom and persisting into convalescence.

Spleen.—The spleen was palpable in 134 out of 148 cases. Three were enlarged to percussion, but not palpable.

The enlargement of the spleen is usually found toward the end of the first week. It seldom extends much below the rib arch and usually maintains this size during the course of the disease, and sometimes after drop of temperature, which not infrequently signalizes a relapse.

Variations in the size of the spleen are occasionally noted during the course of the disease. Decrease in size following profuse intestinal hemorrhage (Gerhard) or after marked remission in temperature (Thierfelder)[27] is seen.

Skin.—Roseola were found in many cases at the first examination; seldom, however, before the sixth day of the disease. As a rule, the rose spots are not numerous, though in some cases quite profuse. The abortive and mild cases generally present few rose spots or none at all. In one mild case no rose spots were found, although daily sought. A severe relapse followed, and on the eighth day a profuse eruption appeared on the abdomen and chest. In another case that pursued a mild course there was an eruption over the entire body and face which persisted for several days, and a fine desquamation followed. This case gave a positive Widal reaction.

This would seem to indicate that no definite statement can be made as to the extent of the eruption in mild and severe infections. Roseola were found in 115 of the 210 cases.

Herpes was present in 3 cases. One of these was complicated with pneumonia. In another the herpes was observed during a relapse.

Sweats were not infrequent, and likewise sudamina, appearing chiefly on the abdomen and chest.

Respiratory Tract.—Epistaxis occurred in 12 cases during the course of the disease. In one, several times. In this patient there were repeated intestinal hemorrhages, which terminated fatally. While the respiratory rate was usually somewhat increased, as a rule, it was not accelerated beyond its normal ratio to the pulse rate, unless pulmonary complications developed. A slight cough was noticeable in a large proportion of the cases. This usually persisted through the greater part of the attack. Actual auscultatory signs of bronchitis were not found in more than half the cases.

Temperature.—As many of the typhoid cases in children are of the mild form, the temperature curve in them is a short one, and, being of shorter duration but possessing the peculiarities of the typhoid curve, both end stages are steeper and shorter and the course in general less regular. While this is true for a little more than half the cases, 82 of the 210 cases ran a temperature lasting from 18 to 55 days, and in 90 there was a temperature for less than 15 days.

Among these cases 16 might be regarded as abortive, in that the patients had a temperature for ten days or less, and were not ailing more than a week before coming under observation.

The average duration of the temperature in all cases was 17.3 days.

The maximum temperatures observed in number of cases given are shown in Table 3:

TABLE 3.—SHOWING MAXIMUM TEMPERATURE AND NUMBER OF CASES.

107.4 degrees.	1
106 . degrees.	3
105 to 106 degrees.	60
104 to 105 degrees.	79
103 to 104 degrees.	42
102 to 103 degrees.	13
101 to 102 degrees.	6

Pulse.—The disproportion first noted by Roger[28] between the pulse rate and temperature observed in adults holds good for later childhood, but in very young children it runs more or less parallel with the temperature (Table 4).

TABLE 4.—THE AVERAGE PULSE RATE FOR DIFFERENT AGES SHOWING A STEADY DECREASE WITH FEW EXCEPTIONS FOR EACH SUCCESSIVE YEAR.

10 years.	100	127
11 years.	100	129
12 years.	108	131
13 years.	90	114

A dicrotic pulse was seldom found, the youngest child showing it being a boy of 4 years. Irregularity was occasionally observed at height of attack.

Blood.—Blood counts were made in many cases, chiefly with regard to the leucocytes. In a number of those complicated with hemorrhages, red counts and hemoglobin estimates were also made.

The weekly average counts of leucocytes were as follows: First week, 6,571; second week, 7,200; third week, 6,740.

The average count for the first week corresponds quite closely to that given by Thayer[28] of 6,442. The counts in the second and third week were probably not numerous enough to be of accurate value. The extremes in leucocyte counts in first week were 3,200, 12,600; second week, 4,400, 9,600; third week, 4,000, 10,000.

A few counts made in cases following hemorrhage, perforation and pneumonia are of interest.

CASE 69.—Hemorrhage nineteenth day. Count after hemorrhage: Whites, 15,800; reds, 3,840,000; hemoglobin, 95 per cent.

CASE 5.—Hemorrhage fourteenth day. White counts on sixteenth day gave 4,500.

Counts following perforation:

CASE 53.—Perforation. Leucocyte count immediately following perforation was 10,800; later in day, 8,800.

CASE 101.—Perforation occurred on the fourteenth day. Count after perforation was 21,600; on the eleventh day it was 17,600.

CASE 177.—On the first day the whites were 5,200. On the sixth day of relapse there was abdominal pain (peritonitis). At 11 a. m. the whites numbered 7,000; at 4 p. m., 8,400.

CASE 191.—On the twelfth day of relapse perforation occurred. Shortly thereafter the whites numbered 8,200; later in the day, 6,000.

CASE 127.—On the tenth day bronchopneumonia set in; on the fifteenth day the whites numbered 2,500; death occurred on the seventeenth day.

---

[27] Thierfelder: Arch. f. phys. Heilk., xiv.

[28] Thayer: Johns Hopkins Hosp. Reports, vol. viii.

Case 183.—Pneumotyphoid. On the fifth day the whites numbered 10,800.

Case 43.—On the first day of pneumonia, the thirty-ninth day of typhoid, the whites numbered 18,500. The case terminated in recovery. There were 3,820,000 reds, 4,668 whites, small mononuclear, 7 per cent.; large mononuclear, 3 per cent.; polynuclear, 90 per cent,; hemoglobin, 90 per cent., at first examination.

Widal Reaction.—The Widal reaction was made in 96 cases, with the following result:

Eighty-six were found positive; 10 were found negative. Of the negative reactions, in 2 it was tried on the first day; in 1, on the second; in 3, on the third; in 2, on the sixth; in 1, on the eleventh; in 1, on the fifty-fourth, after coming under observation.

The negative results can not be regarded as of much value in these cases, as only one or, at most, two trials were made. The negative result recorded on the fifty-fourth day was a week after the drop of temperature to normal.

Of the positive results, 40 were obtained within the first four days after coming under observation. In some a positive reaction was delayed beyond a time when it would ordinarily be considered of much diagnostic value, as instanced by the following:

Case 177.—There was high temperature for eleven days. Four Widal tests made during this time were found negative. On the twelfth day the temperature was normal, when an indiscretion in diet occurred. Relapse followed, and on the second day the Widal was positive. Patient died on the thirteenth day of relapse from peritonitis and pneumonia.

Case 23.—The course was thirteen days, with high run of temperature. Widal test was negative on the second, seventh and eighth days; positive on thirteenth day, or last day of temperature.

Case 136.—The course was twenty days, with high run of temperature. Widal test was negative on second and fifth days, but positive on fourteenth day.

Case 55.—Widal test was partial on seventeenth day, but positive on twenty-third day.

Case 204.—First attack was mild—eighteen-day course. Widal test was negative on eighth day. A relapse of thirty-three days was very severe. Widal test was negative on tenth day of relapse and positive on sixteenth day.

Of these cases it will be noted that in only two could the result have been considered negative, it being found first during the relapse.

A sudden disappearance of the reaction was noted in one case.

Nervous System.—Headache was an almost constant symptom among the older children for the first week or two, being seldom complained of in those under 4 years. It was present in 157 of the 210 children. The very mild cases presented a few symptoms referable to the nervous system, beyond slight headache and dullness. The younger children who, at first, were frequently irritable and restless, later became more or less drowsy. In the moderate and severe cases, in general, there was invariably dullness, a greater or less degree of apathy and drowsiness.

Barrier, Friedrich[29], Seidel[30] and others called special attention to the drowsiness of children suffering from typhoid. Bierbaum[31] stated that drowsiness was a constant symptom, found in older as well as younger children. Gerhard looked on this symptom as characteristic, and considered it due to the narcotic effect of the typhoid poison on the brain.

Fifty-two of the 210 cases presented delirium, in some patients only at night, while others were more or less continuously delirious for short or longer periods. In some, drowsiness alternated with delirium. Occasionally the delirious patients became quite noisy. In a few instances they passed into a stuporous condition, showing the typical *status typhosis.*

Involuntary defecations and urinations are common among these patients, and sometimes continue after the mind has apparently cleared.

Ataxia and jactitation were occasionally observed.

In a few cases marked meningeal symptoms developed, which will be considered under complications.

Genitourinary Organs.—The urine was invariably scant during height of the disease, increasing in quantity with the decline of temperature. An increased secretion of urea and uric acid and diminution in the chlorids were quite constant. Not infrequently albuminuria was found. An acute nephritis did not develop in any case.

Ehrlich's test was made in a large number of cases, with usually positive results. I do not, however, look on it as possessing any special diagnostic value.

RELAPSES.

Curschman states "it has been definitely settled that relapses are the result of a revival of the primary process. Undoubtedly their development is to be attributed to the entrance into the circulation of living typhoid bacilli, which after the primary attack are left behind in various organs, and associated with this more or less complete redevelopment of the local and general typhoid lesions occur."

While Trousseau did not believe that relapses or new attacks occurred, his explanation (made, of course, in antibacteriologic times) of the recurrence of symptoms is similar to the above. He wrote: "It is the same attack, the symptoms of which, temporarily interrupted, recur under the influence of the same morbid cause which produced it in the first instance." He further added: "However complete the symptoms may be, and although the eruption reappears, the characteristic intestinal lesions never recur."

It would seem that such a condition as described by Curschman might often result in typhoid septicemia, in which the local intestinal lesions might not necessarily result.

On the other hand, reinfection of intact Peyer's patches and solitary follicles from typhoid bacilli in the intestinal tract, under favorable conditions, possibly sometimes brought about by digestive disturbances, is not altogether improbable. The frequent close association of relapse and dietetic errors would seem to be more than mere coincidence

Statistics of later years seem to show a larger percentage of relapses in typhoid cases than in earlier times, when the custom of starving fevers was quite generally practiced.

Relapse seems to occur more frequently in children than in adults. Curschman, in analyzing his Leipsic and Hamburg statistics, states that relapse occurred in 13.4 per cent. of the adult cases and in 16.8 per cent. of the children. His Leipsic statistics considered alone show relapse occurring in adults in 12.5 per cent. and in 19.1 per cent. of the children. In striking contrast with the above is the statement of Gerhard that relapse occurs much less frequently in children than in adults.

Of my 210 cases, relapse occurred in 31, or 14.7 per cent.

---

29. Frederick: "Der Abd. Typhus der Kinder." 55, 1856.
30. Seidl: Jena Zeitschrift, vol. iv., Nos. 3-4.
31. Bierbaum: "Der Typhus im Kindlichen Alter," Leipzig, 1861

When relapse occurs in children, it seems to attack girls more frequently than boys. In the 29 relapses reported by Montmollin, 20 were in girls and 9 in boys. In my 31 relapses, 19 were girls and 12 boys.

Ziemssen[32] and Goth found that relapse more frequently follows mild and moderate attacks, about one-fourth of them following severe attacks. Curschman found it to occur 236 times after severe cases and 260 times after mild attacks.

Of the 31 relapses above mentioned, there had been a mild or moderate initial attack in 17 and a severe one in 14.

The period of intermission between the initial attack and the relapse, with the number of cases for each period in which it was definitely determinable, is shown in Table 5.

TABLE 5.—SHOWING PERIOD OF INTERMISSION BETWEEN INITIAL ATTACK AND RELAPSE.

Afebrile period.	Number of cases of relapse.	Afebrile period.	Number of cases of relapse.
1 day.	4 cases.	7 days.	3 cases.
2 days.	2 cases.	8 days.	1 case.
3 days.	3 cases.	10 days.	1 case.
4 days.	6 cases.	14 days.	1 case.
5 days.	3 cases.	21 days.	2 cases.

In 24 cases one relapse and in 2 cases two relapses occurred. The remaining 5 cases were of the recrudescent form.

COURSE AND TERMINATION OF RELAPSES.

Sixteen cases ran a mild course; 4 ran a moderately severe course; 11 ran a severe course; 5 cases terminated fatally, a mortality of 9.7 per cent.

MORTALITY.

The mortality of typhoid in children is considerably lower than in adolescence and in later life, increasing, as it does, with each successive decade. In common with the higher mortality of typhoid in general, in earlier years, that of children was given as quite high by the older pediatricians.

Of my 210 cases, 11 patients, or 5.2 per cent., died.

TABLE 6.—SHOWING AGE, SEX, CAUSE OF DEATH AND DAY OF DISEASE.

Sex.	Age.	Cause.	Day of disease.
F.	14 months.	Intensity of intoxication.	3d. day.
F.	5 years.	Perforation.	Sick 35 days; died on 12th day of relapse.
M.	7 years.	Broncho-pneumonia.	29th day.
M.	8. years.	Hemorrhage.	34th day.
M.	8 years.	Hemorrhage, asthenia.	33d day.
M.	9 years.	Perforation.	Seventh day after relapse. Sick 37 days.
F.	9 years.	Perforation	10th day.
F.	10 years.	Intensity of intoxication.	13th day.
M.	11 years.	Perforation.	18th day.
M.	12 years.	Peritonitis on 6th day of relapse. Lobar pneumonia on 13th day.	Sick 37 days. Died on 15th day of relapse.
F.	15 years.	Peritonitis 16th day. Hemorrhage 23d day.	23d day.

Of the 11 deaths, only one occurred under 5 years, the highest mortality being from 5 to 12 years. Few of the 210 patients were over 12 years, which accounts for the low mortality above that age.

Six of the 11 deaths occurred in males, or 5.6 per cent., and 4.8 per cent. in girls. This is usually reversed, and a higher mortality found in girls. It would seem that sex had but little, if any bearing on the mortality rate.

A consideration of the date of death in these cases shows that one died on the third day, two in the second week, one in the third week, one in the fourth week, four in the fifth week, and two in the sixth week. Two of the deaths in the fifth week and one in the sixth week were during or following relapse.

While the death rate in relapse in general is considerably less than in initial attacks, the mortality in the 31 cases of relapse was more than twice as great as the death rate in the first attack. In the 189 cases in which there was only one attack, there was a mortality of 4.7 per cent. In the relapse cases it was 9.7 per cent.

The deaths in two instances were due to the intensity of the infection; two patients died from pneumonia, in one of whom a previous peritonitis existed; three died from hemorrhage, one of whom previously developed peritonitis, and another after repeated hemorrhage died of asthenia. Four patients developed perforations, two of whom were operated on, and all four cases terminated fatally.

COMPLICATIONS.

Among the 210 cases under observation, several presented interesting disturbances of the nervous system, which would seem to merit brief and separate mention.

CASE 35.—Boy, aged 11. Parent noticed that on the second day of the lad's illness the left eye turned in. The boy came under observation on third day of illness when, among other signs and symptoms, a paralysis of left external rectus was found. On the sixth day the Widal test was positive. Leucocyte count was 5,800. The disease ran severe course of eighteen days. The strabismus improved during convalescence. The boy did not present any other focal symptoms or evidence of meningeal involvement at any time.

The occurrence of ocular paresis in the first week of typhoid infection would seem to be a rare phenomenon. A similar case involving the motor oculi nerve appears in Johns Hopkins Hospital Reports for 1900, described by Emerson,[33] in which the paresis was first noticed on the eighth day.

Three cases showed more or less marked meningeal symptoms.

CASE 161.—Boy, aged 11, complained constantly of headache, and developed marked delirium early. Examination showed marked opisthotonos and rigidity of the trunk, which was said to have existed from the beginning of the illness. This condition persisted during the course of the disease, with enlarged spleen, rose spots and repeated epistaxis. There was a moderate run of temperature. All symptoms subsided after the second week, and the patient recovered.

CASE 206.—Girl, aged 10. There was a high temperature, and stupor alternating with delirium was present. Toward the end of the first week opisthotones developed. The abdomen was tense and the knees were flexed. Rose spots were present and spleen was palpable. All symptoms subsided in the course of twelve days, recovery resulting.

CASE 183.—Girl, aged 2½ years, was sick one week. On first examination the clinical and physical signs of pneumonia were present; the head was retracted. Widal was positive on the following day. The disease ran a severe course of ten days, followed by several days of post-typhoid temperature, terminating in recovery.

Neuritis was found in two cases. Both patients had relapses, toward end of which the neuritis developed. Convulsions were not observed in any case during onset or course of disease, nor in convalescence. While fatuity was occasionally noted, we did not find a case of psychosis.

Circulation.—Although a varying grade of acute myocarditis is noted in about 50 per cent. of the fatal cases, according to Rhomberg, special evidence of this is not infrequently wanting clinically. In severe infections, however, an irregularity, feebleness and intermittency of the pulse are sometimes present, and a slight increase in the cardiac area, permitting the clinical diagnosis of acute myocarditis. The following cases illustrate this:

---

[32] Deutsch Arch. f. klin. Med., vol. xxxiv.

[33] Emerson: Johns Hopkins Hospital Reports, 1900.

Case 143.—A girl, aged 10, in whom the onset was sudden, with high temperature, diarrhea and vomiting, which continued throughout the disease, had a pulse which was always found irregular and feeble, varying in frequency from 136 to 172. She died on the thirteenth day of the disease.

Case 170.—A boy, aged 9, passed through a severe attack of twenty-three days' duration, after which the pulse was noted as irregular. The heart area was increased, with a systolic murmur heard loudest over the base.

Case 122.—A girl, aged 5, ran a high temperature for twenty days, with pulse rate between 100 and 128, and developed at the height of the disease a markedly intermittent pulse which continued into convalescence.

Case 198.—A boy, aged 10, with a moderate run of temperature for twenty-five days, during the last ten days of fever had a sudden drop in the pulse rate, which had averaged from 90 to 120, down to 48. It continued four days between 48 and 64, and gradually increased to between 60 and 80, with irregularity in quality.

None of the patients developed endocarditis or pericarditis.

Respiratory Tract.—Acute angina existed in five cases. In three it developed at onset. In the others on the seventh and eighth days. Griesinger suggested that the atrium of typhoid infection in cases where angina was present from the onset was the throat. This opinion has since been maintained by Baginsky. It is noteworthy that of the first three cases one patient died of perforation on the twelfth day and another of bronchopneumonia. Laryngitis occurred in three cases; in one associated with pneumonia; in another with severe bronchitis.

Six patients developed pneumonia; in two it was lobular and in four lobar. In two of the latter it was present at the first examination; both recovered. Another patient developed lobar pneumonia during a first relapse. The pneumonia ended in resolution and the patient survived a second relapse of typhoid. The fourth patient developed pneumonia of the left upper lobe on the thirteenth day. The patient had already had peritonitis from the sixth day of observation. She died on the fifteenth day. A girl of 2½ years had lobular pneumonia, with meningeal symptoms, on coming under observation. She entered on convalescence on the twelfth day.

The second case of lobular pneumonia occurred on the tenth day of the disease and the patient died on the nineteenth day.

Organs of Special Sense.—The eyes were involved in two cases; in one a strabismus, already referred to, occurred; in the other a phlyctenular keratitis.

Fifteen patients had otitis media; in 14 it involved one ear only and in 1 both ears. A varying degree of accompanying deafness usually cleared up in convalescence. One patient who developed a marked deafness in both ears, and in whom no discharge from ears occurred, subsequently died of perforation. Trousseau looked on deafness in both ears as a favorable symptom, stating that he seldom saw such patients die.

Glands.—In one case an inguinal abscess appeared on left side in convalescence after a nine-day attack. One patient developed painful and tender submaxillary swellings at the end of an eighteen-day relapse, following an initial severe attack of two weeks. In another case similar gland swellings appeared, in convalescence, after a twenty-seven-day relapse. In neither case did suppuration take place.

Skin.—Furunculosis occurred in 4 cases; superficial abscess in 4 cases; bed sores in 2 cases; ischiorectal abscess in one case; extensive cellulitis of neck and back of head, with severe septic symptoms, occurred once, with recovery after operative interference.

Alimentary Tract.—Mercurial stomatitis developed in one case, in which a rhinitis and conjunctivitis also existed. Intestinal hemorrhage occurred in 13 cases, of which 4 patients were girls and 9 boys. The ages and number of cases in each year were as follows: At 4 years, 2 cases; at 6 years, 1 case; at 7 years, 3 cases; at 8 years, 3 cases; at 9 years, 1 case; at 10 years, 1 case; at 11 years, 1 case; at 15 years, 1 case.

Of these, 9 patients recovered and 4 died; one of the latter, however, died from perforation which occurred three days after hemorrhage (Table 7).

TABLE 7.—Showing the Days on which Hemorrhage Took Place in Patients Who Recovered.

	Day of Hemorrhage.	Duration of Disease.
Case 98	13th, 15th, 22d day.	37 days.
Case 25.	20th day.	32 days.
Case 69.	19th day.	21 days.
Case 142.	11th day.	28 days.
Case 157.	14th day.	21 days.
Case 76.	16th day.	18 days.
Case 117.	35th day.	54 days.
Case 180.	7th day of relapse.	34 days.

FATAL CASES.

A boy, aged 11, had a copious hemorrhage consisting of bright red blood and dark clots on the fourteenth day. On the seventeenth day perforation occurred and the boy died on the eighteenth day. A boy, aged 8, had been sick four weeks; he is said to have passed blood daily for a week. While under observation, he had no hemorrhage. Epistaxis occurred once. The boy died twelve days later from asthenia. Another boy of the same age had a copious hemorrhage on the thirtieth day and another on the thirty-fourth day; he died in collapse on the forty-second day. A girl, aged 15, developed peritonitis on the eighteenth day. There was copious hemorrhage on the twenty-third day and she died a few hours later. The temperature was subnormal and the pulse 150.

Montmollin reported hemorrhage in 14 out of 295 cases, 4 resulting fatally. Curschman records hemorrhage in about 1 per cent of his cases in children, which would seem unusually low, unless fatal cases alone were considered. Peritonitis developed in 6, or 2.8 per cent., of the 210 cases. Of these patients, 2 were males and 4 females. The youngest was 5 years; the oldest 15 years.

Following is brief history of individual cases:

Case 39.—Boy, aged 11. Temperature was moderate; there was marked tympany, diarrhea and considerable tenderness of left iliac region. On the fourteenth day he grew very restless and had a large hemorrhage, passing dark clots and bright red blood. Temperature was unchanged at the time; pulse slightly accelerated. On the seventeenth day he complained of pain in the abdomen; tympany increased and liver dullness diminished; the abdomen was tense and painful. He vomited frequently. A diagnosis of perforation was made. He was operated on and died the same day.

Case 53.—Boy, aged 9, had a moderate but erratic temperature for nineteen days and an afebrile period of five days. A mild relapse of ten days followed. After five days of normal temperature indiscretion of diet occurred. The following day temperature was 103.4; pulse 134. He complained greatly of abdominal pain and presented Hippocratic fascies. There was frequent vomiting. Examination showed a distended, hard abdomen, with great tenderness. Liver dullness was diminished. Leucocyte count on the morning of abdominal pain was 10,800; several hours later, 8,800. A diagnosis was made of perforative peritonitis. The boy died five days later.

Case 101.—Girl, aged 9. The disease ran a moderately high temperature. She vomited on the tenth and thirteenth days. On the fourteenth day she complained of severe abdominal pain and vomited often and had hiccoughs. Abdomen at first sunken and hard, became distended, tense and very painful. Liver dullness disappeared. Leucocyte count on fourteenth day was 21,600; on the fifteenth day, 17,600. At 8 a. m. of the fourteenth day temperature was 99.6, and pulse 92. At 11:30 a. m., after complaint of abdominal pain, temperature was 101 and pulse 136. A diagnosis of perforation was made. The girl died on the sixteenth day.

Case 159.—In a girl aged 15, the disease ran a high temperature. She vomited on the seventeenth day. On the nineteenth day she complained of abdominal pain. In the morning the temperature was 100.6; at 1 p. m., 105.6, and at 8 p. m., 99.4, dropping to subnormal, where it remained till the following morning. Thereafter she had high temperature, with maximum of 106. There was frequent vomiting, abdominal distension, rigidity and tenderness. The Hippocratic fascies was present. On the twenty-third day she had a large hemorrhage and died the same day. The diagnosis was perforative peritonitis, with intestinal hemorrhage.

Case 177.—Girl, aged 12. The first attack was severe, lasting eleven days. There was an afebrile period of one day. After a dietetic error a relapse occurred on the following day. On the sixth day of the relapse she had severe pain in the abdomen, which became distended and tense, and was exquisitely tender. Liver dullness was present. A leucocyte count after complaint of abdominal pain was 7,000 at 11 a. m.; at 4:30 p. m. the same day it was 8,400. The girl developed pneumonia of left upper lobe on the thirteenth day. She died on the fifteenth day. Diagnosis was peritonitis and lobar pneumonia. Four Widal tests made in this case in the initial attack were negative. It was found positive on the second day of relapse.

Case 191.—Girl, aged 5. First attack lasted nineteen days and was moderately severe. Then there was an afebrile period of three days. Diet was increased and a relapse began on the fourth day. The relapse ran a high temperature. During the early morning of the twelfth day of the relapse she complained of pain in the abdomen. Pulse was 160; temperature, 103.8; respirations, 40. She vomited. Examination showed a distended, hard and tender abdomen. The knees were flexed. Liver dullness was diminished. Hippocratic fascies was present. Leucocyte count was 8,200 in the morning; at 4 p. m. it was 6,000. A diagnosis was made of perforation. She was operated on the same day, and died several hours later.

TREATMENT.

The treatment employed in these cases consisted in proper hygiene, and care of the patient, appropriate diet and symptomatic treatment, including hydrotherapy; in some instances, intestinal antisepsis and the treatment of special symptoms and complications as they arose.

The environment and care of the little patients was looked after, when possible, by trained nurses, whose intelligent co-operation in the care of typhoid fever is invaluable.

The diet given during the course of the disease was chiefly milk, barley and strained oatmeal gruels, albumin water, custard, chocolate, eggnog, and ice cream, and drinks of orangeade, lemonade and water.

There seems to be a tendency to enlarge the diet of typhoid patients and to broaden it into quite a menu. A study of the diet in these 210 cases leads me to believe that it is quite an unfortunate venture, so far as children are concerned. The administration of egg, whole, in any form, seems intolerable in a large proportion of children. On the other hand, the white of egg, as albumin water, is always well borne. When eggnogs are given during the first part of the disease, the intestinal symptoms are intensified. After discontinuing their use, the temperature, in some instances, would seek a lower level. They seemed to exert an especially unfavorable influence in defervescence and during the first days of convalescence, as instanced by the following: A child of 5 years, after running a temperature for 22 days, received, in addition to the regular liquid diet, eggnog before the temperature was fully normal. Temperature arose the following day and continued high for twelve days. In a child of 6 years, typhoid ran a course of 30 days. Four days were afebrile, and eggnog was added to the diet. A relapse of nine days, with high temperature, followed.

While milk is not the appropriate diet for infants, or for very young children, with a catarrhal or follicular enteritis, it seems to be well borne in typhoid patients of the same age, provided it is diluted from one-half to two-thirds with a cereal gruel or lime water. It is not, however, well tolerated when given as whole milk; the stools become curded and slimy, and tympany increases. This is frequently true with older children, and similar dilutions of milk are desirable. Where greater dilutions are necessary, they may be used.

From a close study of the action of diet in these cases, milk, diluted for infants and young children, as indicated, would seem to be the best diet for children suffering from typhoid fever.

Albumin water is also a suitable part of the diet, as is likewise the usual cereal gruel diluents, as barley water and rice water, to be given, however, more as drinks than to take the place of milk.

Ice cream at times seems to be well borne; at other times the intestinal symptoms become more marked.

The care of the diet in the first days of convalescence is as important as at the height of the attack. Too frequently errors at this period have sad consequences, as instanced by the following: A girl of 12 years passed through a severe attack of 11 days' duration, followed by an afebrile period of one day. She received toast, and temperature rose next day to 105, the beginning of a relapse, on the sixth day of which she developed peritonitis; on the thirteenth day lobar pneumonia, and she died on the fifteenth day. A girl of 11 years had a mild attack of 20 days, with temperature the greater part of the time below 100. After one day of normal temperature she received egg and toast. The temperature rose on the following day, and she had a severe relapse, lasting 33 days, with maximum temperature of 105.

If a patient can continue to live on a liquid diet during the severe course of the disease, they certainly can do so after the temperature is normal. It would appear that it is seldom necessary to disturb this afebrile period by an increase in diet until the patient has passed beyond a time when it is likely to do harm, which time I would place at ten days. Then I would gradually increase the diet, remembering that infants and very young children will not do badly if milk constitutes a greater part of their nourishment.

In cases of intestinal hemorrhage the diet was limited in quantity and was confined to whey, albumin water and beef juice. In cases of perforation, nutrient enemas were used.

Hydrotherapeutic measures employed consisted in tubbing, sponging and the cold pack. Tubbing was used in practically all cases, unless some contraindication existed which rendered it inadvisable. This method is especially suited to children. They are easily transferred from bed to tub, and after the first few tubbings seldom offer any resistance to it.

While the temperature was the usual guide to its employment (103.5 to 104 by rectum), it was also resorted to in the presence of marked nervous symptoms, even when the temperature was at a lower level. The nervous symptoms are probably as important an index to its use as the temperature, as they seem to be a safe guide to the intensity of the infection. Patients with marked nervous symptoms, however, commonly run a high temperature in typhoid, so that, in general, the temperature, except in exceptional instances, forms a reliable indication for the hydrotherapy.

The temperature of the bath at first was about 90 degrees and gradually cooled to 80 or 75, the bath lasting from 10 to 20 minutes, the patient being gently rubbed during this time. It would hardly seem necessary or advisable to resort to the low temperatures of the water as originally recommended by Brandt. A decided lowering of temperature, varying from 1 to 3 or 4 degrees, is obtained by above bathing temperature first recommended by Ziemssen.[34]

While the number of tubbings in 24 hours depended on the temperature, I am inclined to think that we sometimes overdo it and tire our patients. A child with typhoid requires rest, and should be manipulated as little as is consistent with the condition.

In addition to the hydrotherapeutic measures mentioned, in cases of intense intoxication high enemas of salt solution were administered from every four to six hours, in quantities of from two to eight ounces, according to how they were retained. They seemed to be of considerable advantage by increasing elimination, especially renal.

Intestinal antiseptics were given in a number of cases, among them acetozone, salol, guaiacol, benzozol, and calomel; the latter also for its laxative effect. Of the fatal cases, of whom ten patients were under treatment (the eleventh patient dying twelve hours after coming under observation), five were receiving intestinal antiseptics. Of these, 3 received acetozone, 1 salol, and 1 calomel. Of the 210 cases, 45 received acetozone, 15 salol, 7 calomel, 2 guaiacol, and 2 benzozol. One hundred and thirty-nine did not receive any intestinal antiseptics.

It is probably a coincidence that the mortality among those getting intestinal antiseptics was 7 per cent., and among those not receiving them 3.8 per cent. This is probably due to giving intestinal antiseptics in severe cases, with the hope of exerting some influence on the intestinal changes. However, the use of intestinal antiseptics did not seem to be of any special value in any of the cases.

Of the special symptoms, those referable to the nervous system were invariably favorably influenced by hydrotherapy, as was likewise the circulation. The pulse usually showed, where rapid and feeble, considerable improvement following a tubbing, both in quality and diminished frequency.

In cases of constipation in first week, small doses of calomel or castor oil were used. At a later period, the enema was employed, although at times calomel and castor oil in small doses were also given.

Diarrhea was seldom sufficient to call for special treatment beyond attention to diet, as the adding of lime water to milk, and avoidance of broths.

When tympany was marked the usual turpentine applications, and salt enemas, or rectal injections of emulsion of turpentine in equal parts of milk of asafetida and liquor camphor were used.

In cases presenting marked cardiac weakness, stimulants, chiefly strychnin and whisky, were administered. The pneumonias received no special treatment beyond the employment of cardiac stimulants, when indicated, strychnia being used hypodermically when necessary; also whisky or brandy.

In hemorrhage, the usual methods were used: the ice coil or bag, morphia hypodermically, or opium and acetate of lead by the mouth, restriction of diet, and elevation of foot of bed.

Of the cases of perforation, two patients were operated on, but died, as did those not operated on.

Of the medicinal measures, an opiate was given as necessary, and rectal feeding employed.

DISCUSSION.

Dr. Arthur W. Fairbanks, Boston, stated that he has been interested in noticing that the rule of differential diagnosis of typhoid and tuberculosis that is of so much value—the disproportion between the pulse and temperature—does not apply in the same degree to children. The Germans have always placed great emphasis in the adult on the slowness of pulse in proportion to temperature in typhoid fever, and it is a very striking occurrence. The pulse is near the normal, 80 or 85, and temperature from 101 to 103 and 104, and possibly higher in typhoid. In tuberculosis it is exactly opposite. In the vast majority of cases the pulse is extremely rapid, out of all proportion to the temperature. In children that fact does not seem to apply. In typhoid fever the pulse seems to follow the temperature. The leucocyte count is of much value in these cases. Dr. Fairbanks recalled that in the summer of 1904, in the holidays, a large number of children were affected with diarrhea. In one case he could find no rose spots and no signs of typhoid fever. There was irregular temperature. There seemed to be no evidence of typhoid fever, but the leucocyte count pointed to typhoid. The bacteria found during a search for Shiga organisms, responded to all the tests of the typhoid organisms. This indicates the value of the leucocyte count in these cases. There is a reduction in the leucocytes, a leucopenia, in typhoid, while in other cases likely to be mistaken for this disease there is almost invariably an increase, a leucocytosis.

Dr. W. J. Butler, in reply to questions, stated that in typhoid fever in infancy the only positive way of making the diagnosis under all circumstances is by the Widal reaction, or finding the bacilli. The test made with dried blood is quite as satisfactory as with the fresh serum.

SOME CAUSES OF FAILURE AFTER GYNECOLOGIC OPERATIONS.*

WILLIAM E. GROUND, M.D.
SUPERIOR, WIS.

GENERAL CONSIDERATIONS.

Our mission as gynecologists is to cure women of their diseases, and any procedure, however skillfully executed, is a failure if a cure is not effected.

Whether gynecology is to continue to be a living, growing specialty and to redound to the benefit of womankind, as its founders originally conceived, will depend very largely on whether it can be rescued from the ultra surgical, and gynecology not be made a synonum for surgery. The brilliant results obtained by general and gynecologic surgery have been so fascinating that many of the most brilliant of our profession have been so charmed by the glitter as to abandon less luminous fields and devote their entire energies to the development of this department of therapeutics, along purely mechanical lines. While, as has often been said, gynecologists were the first to blaze the way to successful surgery within the abdominal cavity, general surgeons have not been slow to take advantage of this, until now the uterus and its appendages are considered their legitimate field. It is true that many of the most satisfactory results are attained by major operations, still gynecology does not end with these. Gynecology is defined by a modern medical lexicographer as that branch of medicine which treats of women's constitution and diseases. By this it will be seen that the treatment of diseases of women does not end with the treatment of organs peculiar to her, nor necessarily with a special operation, but of the woman as a whole.

---

[34] Ziemssen and Immerman: "Die Kaltwasser Behandlung des Typhus Abdominalis," Leipsig, 1870.

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

I do not mean to infer that a woman is not especially affected by the organs peculiar to her, but that a mere readjustment of a rather unimportant organ without further effort will cure her of her ills, I very much doubt. It is too much the tendency nowadays, to do more or less surgery on a woman, correcting certain lesions, and to send her away cured; but she comes back to us or to some one else and says she feels the same as before the operation and is no better—sometimes worse. We examine her, and find the perineum which we repaired intact, the uterus on which we did a fixation or suspension operation of some sort in its proper position; the ovary that we patched up and left is seemingly doing well; perhaps we removed the appendix and still the woman complains. We tell her that her pelvic organs are all right and that she ought to be well; and she will be in time if she has no organic disease of other important organs, or if she does not become discouraged and sink back into a condition of semi-invalidism, or become involved in the machinations of the osteopath or Christian scientist. I have known many patients who had undergone successful surgery, and not getting the proper relief that they expected, drift into the hands of some pretender, and the surgeon not only does *not get the* credit due him, but is actually blamed for doing unnecessary operations. It is important, therefore, to bear in mind that women have other organs besides the perineum, cervix, uterus, tubes and ovaries, and above all, that they have very susceptible nervous systems, capable of being influenced by many agencies apparently remote.

So much for the less apparent reasons; and now as to the more tangible reasons why women do not recover after they have undergone certain operative procedure, calculated to prevent or to cure pathologic conditions. Fully realizing the enormity of this task, I will limit my remarks to a few of those most frequently met in the pelvis.

PELVIC FLOOR DAMAGE.

Beginning with the lesions in the order that they present themselves to the gynecologist, we will first consider the perineum and pelvic floor. *Pregnancy, parturition* and the puerperium may not be strictly gynecologic conditions, but that they rapidly become so is conceded. We have only to refer to our gynecologic case records to learn how very frequently women date their ill health to their confinements, often to the first. As pointed out by Hirst a few years ago, this is a most frequent cause of ill health in women. From the time a woman becomes pregnant until she has entirely recovered from her delivery, she is subjected to many and violent influences. First, the disturbances of metabolism and the toxemias; the disturbances of the dynamic relations of the abdominal viscera by the growth and pressure of the gravid uterus and the traumatisms and infections accompanying and following delivery. It is practically impossible as conditions now exist, for a woman to be delivered of a child at full term without more or less injury to the pelvic floor, vagina or perineum. As Edgar says: "When we remember that the outlet of the birth canal, with a diameter of from 1 to 1½ inches is suddenly dilated until a ring of from 10 to 12 inches is produced, it is not hard to understand why injury is inflicted."

These injuries do not take place, as a rule, where they are plainly visible. The line of laceration follows the direction of least resistance, or at the point of greatest pressure. Tears in the vaginal mucous membrane and perineum may not be at the same point. Lacerations of the pelvic floor (levator ani muscle and fascia) may occur immediately under the tear in the vaginal mucous membrane, or it may be submucus at another point, or the musculature of the pelvic floor may be extensively lacerated and the skin and mucous membrane remain intact. The consequences of these lacerations depend entirely on the structures injured. If confined to the skin and perineum, no harm will follow, so far as support is concerned, but if the deeper tissues, the levator ani muscles are involved, there will occur loss of the perineal flexure of the rectum and vagina, with recession of the vagina and anus from the pubic arch, rectocele, cystocele, prolapsus uteri and uterine retrodeviation, subinvolution of the uterus and vagina and splanchnoptosis, followed by dynamic disturbances of the influence of intra-abdominal pressure, supervention of reflex phenomena and a state of general ill health will be instituted.

Too many operators lose sight of the fact that the perineum and the pelvic floor or diaphragm are different structures, developmentally, anatomically, physiologically and pathologically, and anatomists have repeatedly called attention to the disassociation of these two structures. In speaking of the anatomy of the pelvic floor and perineum, I shall be compelled to quote very freely from Peter Thompson on "The Myology of the Pelvic Floor." I am aware that many gynecologists are now teaching the new anatomy of pelvic support, but that the majority of the profession are sufficiently awake to the importance of the exact nature of these lesions I very much doubt.

The pelvic floor is for the support of the superimposed viscera, while the perineum is simply a common meeting point for muscular and aponeurotic structures entirely below and external to the pelvic floor and has to do with the mechanism of the closure of the clefts of the visceral outlets—the sphincters. Those muscles having to do with sphincteric action are developed from the primitive sphincter cloaca, while those forming the pelvic diaphragm were originally the muscles of the caudal end of the vertebral column, and are developed from the primitive flexors and adductors of the caudal vertebræ.

The pelvic floor is composed of four paired muscles—the ischiococcygeus, the iliococcygeus, the pubococcygeus and the puborectalis. These muscles take their origin, roughly speaking, from around the brim of the true pelvis, and are inserted into the sacrum, coccyx and median tendinous *raphe*. The pubococcygeus and the puborectalis form the most important constituent element of the pelvic *support*. The pubococcygeus arises from the back of the body of the pubic bone along an oblique line which extends from the lowest limit of the symphysis outward toward the obturator canal and, to a limited extent, from the obturator fascia. From this origin the fibers pass back by the urethra, vagina and rectum and are inserted by a tendinous expansion to the ventral surface of the lower part of the sacrum and coccyx. The puborectalis, or sphincter recti of Holl, arises from the back of the lowest part of the symphysis, under cover of the pubococcygeus, from the upper layer of the triangular ligament, and from the pubis immediately beneath the symphysis. From this origin the fibers pass around the lower rectum, meeting with the fibers from the opposite side, to form a loop or girdle which slings the rectum and vagina up under the pubic bone.

The puborectalis keeps the rectum and vagina pulled forward under the pubic bone, so that the anus occupies a position on a line from one tuber ischii to the other and midway between the tip of the coccyx and the symphysis pubis. This is the position when the muscle is intact, but when it is lacerated or has lost its tone it allows the perineal body to recede, and the perineal flexure of the rectum and vagina is lost. This is the muscle that receives the major part of the injury sustained during delivery.

If the practice is made of investigating the tonicity of the puborectalis in all vaginal examinations, both before and after parturition, the difference can readily be determined. In women who have not borne children this muscular band can be felt tense and firm, as it passes along by the side of the vagina just within the introitus. In the vast majority of cases after delivery there is a condition of relaxation, of flaccidity and loss of tone, often with little or no resistance to backward or lateral pressure with the finger until the ligaments or pelvic bones are reached. Breaks in the musculature of the pelvic floor can frequently be distinctly felt. I have observed the physical condition of the muscle and fascia before and after delivery in the same woman and noted the difference. These observations were systematically made, not only immediately, but months after labor, and the muscles rarely recover their tone, even in those cases in which immediate repair had been done. These observations were made not only with the woman lying quietly in bed or on a table, but standing. The erect position brings out the contractile power of the levator ani and the integrity of its fascia, and with the finger in the vagina this muscular band can be so studied that any interruptions in its continuity can be noted. This can often be graphically demonstrated by placing a wax phallus in the vagina and asking the woman to contract the pelvic floor and noting the indenture.

This led me to believe that almost every woman during her confinement suffers injuries from which she does not recover, and that immediate suture of apparent lacerations does not restore pelvic support in the vast majority of cases. Certainly repair work attempted on a bed, without proper assistance, retractors or a good light, is little more than a farce so far as restoring the function of the pelvic floor is concerned.

I do not wish to be understood as not favoring immediate suture. Such operative procedure is not only necessary to prevent infection, to restore sphincteric action and pudendal symmetry, but accurate readjustment to the normal position of the musculature is essential for the full restoration of pelvic support, is attainable to the fullest degree only with the immediate operation or, at most, operation within the first few days. The muscle and its fascia at once begin to retract and atrophy so that a secondary operation, however well done, can not restore function to the same extent. An efficient immediate or intermediate operation is possible only with the patient on the table, with good light, retractors and assistance. Careful examination of the parts must be made, and the original anatomic elements united. Suturing the superficial rents in the skin and mucous membrane, passing through a promiscuous mass of tissue beneath and uniting structures of a dissimilar nature will not restore the pelvic floor nor prevent vaginal prolapse. Who would attempt to cure hernia by simply suturing together the skin over the abdominal ring, and pelvic herniation is practically what happens when the muscular and fascial structures of the pelvic diaphragm are impaired.

Furthermore, my observation teaches me that, even after a careful immediate suture, a considerable percentage of cases will require a secondary operation; for, unless the tear in the vaginal mucous membrane and that in the musculature is at the same point, the sutures will not make a union of proper structures. When the puborectalis has been lacerated at a different point from that of the skin I have not hesitated to cut down and suture its ends with buried sutures.

ABDOMINAL PTOSES—RETROVERSION.

Whether by the inefficiency of immediate suture or its omission, or the lack of proper secondary repair, where tissues of a dissimilar nature are united in a cicatricial mass, and original anatomic structures left apart, normal physiologic support is not secured. Prolapse and telescoping of the vagina and uterine retroposition naturally follows. Further than this, gravity and intra-abdominal pressure leads to ptoses of the viscera and tugging on the normal peritoneal ligaments of the liver, stomach, kidneys and intestines. It is a well-known fact that little pain is produced in operations within the abdomen under local anesthesia if the peritoneal attachments of the organs, especially the bowels, are not pulled on. Even under anesthesia we readily notice increased disturbance of the heart and respiration the minute we begin pulling on the peritoneal processes. A very little relaxation of the pelvic floor would allow sufficient tension to be placed on the peritoneal ligaments (which are the true supports) of the uterus, bowels, kidneys and stomach to produce the symptoms of splanchnoptosis. Intra-abdominal pressure is the result principally of muscular contraction and gravity, to which is added, especially in women, faulty dress. Woman's dress is almost as trying on the pelvic diaphragm as parturition, but with the two combined is it any wonder that women are ailing?

The startling frequency with which visceroptosis is met in neurasthenic conditions in women is well known. Neurasthenia is much less common in men, but those I have had experience with have been where there was ptosis of one or more of the abdominal viscera.

Led by the teachings of Theilhaber, Winter, Landau, Freudenberg, and later of Pfannensteil and Wormser, we are becoming more and more cognizant of the fact that uncomplicated retrodisplacements of the uterus give rise to few symptoms; and yet in nearly every medical society meeting there is a paper or discussion on some pet operation for retroplaced uteri. There are some 50 operations or devices for overcoming retrodisplacement, which, to my mind, shows the utter futility of these operations *per se* in relieving symptoms. Early in my experience I was struck with my inability to cure my patients of symptoms supposed to be due to retroversion. I then began to keep fuller records of the after-history, and I found that few patients were cured or even benefited. Most of these patients passed from observation, but I have the records of 48 cases on which to base my conclusions. Later I began to do more thorough work on the pelvic floor, independently of or in connection with, the versions, as the individual case seemed to demand, to correct visceral ptosis and to keep the organs in position by external support, gymnastics and proper dress and posture; in other words, I followed up my cases, and the results have been eminently satisfactory.

A normally developed uterus that is not infected, that is movable and is not in a condition of prolapse so as to pull on its peritoneal ligaments will not produce symptoms, no matter what position it occupies. On the other hand, a traumatized, infected or fixed uterus will cause symptoms, no matter in what position it is placed; and this is true of the abdominal and pelvic viscera as a whole. As soon as any viscus becomes infected or injured or drags on its attachments, its blood and lymph circulations are interfered with and it has a tendency to become fixed. This fixation interferes with peristalsis and adds trauma to the nerve supply and irritation to the nerve centers.

Puerperal lesions of the pelvic floor, vagina and cervix produce nerve irritation and lead to infection of the uterus, tubes, ovaries, broad ligament and pelvic peritoneum, either by continuity of tissue or through the lymphatic circulation. When the uterus is infected, heavy and traumatized and its pelvic-floor support diminished, it recedes into the pelvis, pulls on its intraperitoneal ligaments and forms adhesions with surrounding structures. Taken as a whole, very few women escape infection after abortion or delivery at term, not necessarily of a severe type, but so mild as often to create little notice at the time. Later there will be cicatricial contractions in and around the uterus, and corresponding symptoms follow. I have observed many cases of retroversion in young women that never produced symptoms until pelvic-floor relaxation occurred, unless infected by the gonococcus or pregnancy ensued with its consequences. As first pointed out by Schultze, the position of the uterus is that of mobile equilibrium and is pathologic only when restricted in its freedom of movement. This wide range of physiologic mobility is maintained principally by the pelvic floor and pelvic peritoneum. The so-called uterine ligaments are normally in a state of relaxation, and simply resist excessive movement. Consequently, those operations are the most successful that inflict the least injury on the peritoneum, produce fewer adhesions and allow most physiologic mobility.

CONSERVATIVE OPERATIONS ON OVARIES.

Another source of failure after intrapelvic operations is the so-called conservative operations on ovaries. It is admitted by all that the influence of the ovary on the growth, development and very likely the life of the woman is very important; that in all operations about the pelvis it is advisable to conserve all the ovarian tissue possible; that the uterus is merely a fetal receptacle and, in health, has no influence on the normal cycle of a woman's life. Furthermore, it is admitted, I believe, that the vast majority of the destructive lesions of the ovaries have their inception in metritic processes, engendered by the introduction from without of certain micro-organisms known to have a deleterious influence. It is very much of a question whether, after a uterus once becomes thoroughly infected, it ever quite regains its normal condition. Especially is this so of gonococcal infection. Postabortive and postpuerperal sepsis, while more frequently recovered from or more amenable to treatment, often leave a train of pelvic symptoms due primarily to the infection. From this source the ovaries become involved either by continuity of tissue through the corporeal endometrium and the Fallopian tubes or by way of the lymph stream. According to Porier, the lymphatic vessels of the uterus form four or five trunks which appear beneath the cornua. These vessels at first follow the terminal segment of the uterine artery, then pass beneath the ovary, where they are joined by vessels from this gland. Then they run in the suspensory ligament of the ovary, and with the blood vessels surround the ovary, in their passage to the lumbar glands.

Consequently, in those infective processes in which the question comes up, at the time of operation, regarding the necessity of sacrificing one or both ovaries, in part or whole, or the removal of one ovary and part of the other, and it becomes very much of a question after removing one ovary whether it is possible to save the other.

Under such circumstances we will be much more likely to conserve ovarian tissue by doing a supravaginal amputation of the uterus and excising the Fallopian tubes and the accompanying lymphatic trunks than by doing conservative work on the ovaries alone and leaving the uterus. Furthermore, in those cases in which it becomes necessary to perform a double salpingo-oöphorectomy for septic conditions, there is no question in my mind as to the advisability of removing the uterus at the same time. This has been my practice for several years, and my results have been eminently satisfactory. Leaving a uterus, the source of pelvic pains, leucorrhea and infection, will render other operative procedures of doubtful utility. After the ovaries are gone, there is little, besides sentiment connected with the uterus, of value. Besides, the hysterectomy allows us to do cleaner and better work, with fewer postoperative adhesions to cause pain, intestinal obstruction, reflex and general disturbances, and failure to effect a cure.

It is my intention to follow up this subject pertaining to other abdominal operations in future papers.

DISCUSSION.

Dr. J. H. Carstens, Detroit, said that too often patients are operated on and for various reasons are not cured. Once in a while the operation is a poor one, or the technic is poor and complications arise, or union is not perfect and adhesions form, or something else happens, or there is shock or some other condition which causes great suffering. The principal reason is that physicians do not make a correct diagnosis. Because the patient is a woman, it is taken for granted that the trouble is in her uterus, ovaries, tubes or perineum. Physicians are apt to forget that women have general ptosis of the abdomen, that they may have floating kidneys, gallstones, appendicitis, syphilis, neurasthenia, and many other things, just like men. They neglect to look for these things and the result is that operations are not successful. Dr. Carstens urged the necessity of a more thorough diagnosis and a more thorough systematic investigation of every case. Many patients are hurriedly taken to a gynecologist for operation. Sometimes there is a fibroid or a cirrhotic ovary, or an ovarian tumor which is causing pain; the gynecologist finds that condition and thinks that it ought to be removed, that it causes some of the symptoms, which probably is true. It is removed, not because the woman's life is in danger, but because she is suffering. The patient comes back later, but is not cured of some of her symptoms. She may have had gallstones. The family physician may have overlooked the nature of her trouble or he may not have told the operator of her attacks of pain. Perhaps she takes improper food; therefore gynecologists must be more thorough in the examination of a patient. Often the general practitioner takes the patient to the gynecologist and promises her relief. Dr. Carstens does not promise his patients everything, because if they do not get the promised relief the operator is blamed.

Dr. D. H. Craig, Boston, said that Dr. Carsten's remarks can be epitomized as follows: 1, Inefficient operating; 2, insufficient operating; 3, excessive operating; 4, insufficient preparation; 5, insufficient convalescence. If gynecologists will take cognizance of these five factors in every case it will help to do away with failures in the majority of cases. The length, troublesomeness and seriousness of convalescence are in exact inverse proportion to the time the operator spends in getting his patient ready for operation. Adequate preparation means shorter and better convalescence. Hasty preparation means protracted convalescence, and frequently it means the drifting of the patient into a state of discouragement, and the operator is credited with a failure. Did the gynecologist pay sufficient attention to the preparation of the patients morally, mentally and physically, he would go far toward avoiding failures.

Dr. J. T. Walls, Portland, Ore., declared that lacerations following parturition are frequently overlooked; such patients should have early attention after confinement. If the physician knows there is an injury he should advise its early repair, because malignancy is likely to set in. Dr. Walls has found few cases of cancer of the cervix that could not be traced to an old laceration. Small lacerations should not be overlooked, as they frequently produce much systemic disturbance, and he makes it a rule to repair all lacerations when he has an opportunity. In cases of long standing the uterus should first be curetted, and the patient given time to recuperate and the endometrium to become normal before doing a trachelorrhaphy. The patient should be kept quiet until union is complete. Dr. Walls avoids using tampons of any kind; he prefers instead the use of antiseptic gelatin suppositories, using them at night only; he has the patient insert the suppository herself. This, he finds, serves the double purpose of tampon and douche. In the morning he has the patient cleanse the parts externally by the use of warm soapsuds, using a cloth, omitting the douche entirely.

Dr. V. J. Hawkins, St. Paul, Minn., said that no matter how much the cervix is lacerated, if it is covered by normal mucous membrane no symptoms will arise unless there is an infection. So far as consultants are concerned, patients should not be taken to the surgeon for the purpose of having a certain operation performed. If a patient of Dr. Hawkins is not getting along well, he asks for the privilege of a consultation, thus placing both himself and the surgeon in a good position, because their opinions of the case may differ. There is so much chance for a difference of opinion that it is unwise to tell patients that one will call in a surgeon to have a certain operation performed. That might not be the cause of the trouble. Dr. Hawkins said that the surgeon should not expect that every case brings with it a large fee; nor should he imagine that because the physician does not tell him everything, that he does not know. In many of these cases the trouble is caused by autointoxication or malnutrition, and that must be gotten rid of before results can be obtained. Physicians should get away from the belief that lacerations of the cervix cause cancer or other serious trouble, unless there is an infection.

Dr. D. C. Newman, Spokane, Wash., stated that in his experience these lacerations of the cervix rarely become covered with normal mucous membrane. They may be patched up for a while, but they soon become infected and then there is trouble. Dr. Newman thinks that Dr. Carstens hit the nail on the head when he said that the reasons these operations are a failure is because gynecologists do not treat the patient, but only the uterus and appendages.

Dr. W. E. Ground said that it is important to follow up these patients after operation, teaching them how to live, to dress, and even how to stand and to walk, if the best results are expected.

Proprietary Preparations with Incompatibilities.—But let me warn you to place no faith in the pharmaceutical monstrosities which are said to contain pepsin combined with pancreatin, with which it is positively incompatible, nor those in which it is combined with wines or any preparation of alcohol which, except in the weakest dilutions, interfere with its action.—Boardman Reed.

ETIOLOGY AND TREATMENT OF SO-CALLED ENDOMETRITIS.*

ERNEST F. TUCKER, M.D.
PORTLAND, ORE.

It is with a feeling of great diffidence that I bring before this section such a common-place subject as endometritis, but I feel justified in doing so from the fact that, taking at random six different modern text-books, I find given twenty-seven different kinds of endometritis; out of these twenty-seven varieties, there is no one variety which is mentioned in each text-book. There are three varieties (exfoliating, gonorrheal and septic) which are mentioned in four; four varieties (atrophic, hypertrophic, simple chronic and fungous or fungoid) in three; eight varieties (hemorrhagic, hyperplastic, glandular, interstitial, polypoid, simple, tuberculous and senile) in two, and ten varieties (catarrhal, decidual, menstrual, diphtheritic, infectious, syphilitic, virginal, puerperal, putrid and villous-degeneration) mentioned once each in six different text-books. If gynecologists were earnest, serious students to-day and just beginning their gynecologic studies, they would throw up their hands in despair at twenty-seven different diseased conditions of one small tissue, each entitled to a separate pathology, symptomatology, diagnosis, prognosis and treatment; for these terms, strictly speaking, are not interchangeable. I have particularly tried to avoid using different terms that might mean the same thing, or I might have added several varieties more. If these twenty-seven varieties of endometritis really exist, they should be described in each text-book; if they do not, they should be cut out.

I do not wish to take up time with a description of the gross or minute anatomy of the endometrium, but will call attention to the fact that it differs materially from any other structure in the body; that it is not a true mucous membrane; that it is a glandular structure intimately connected with the muscular tissue of the uterus, and, therefore, is tremendously influenced by any changes which take place in the uterus; that the endometrium of the body and that of the cervix are histologically different, and that I am speaking particularly of that of the body. Its main function is undoubtedly connected with the development of the fertilized ovum. The endometrium is by nature a hemorrhagic tissue, as is proved by the flow of the menstrual period which is merely the result of an overcongested tissue and is Nature's remedy for its relief. This structure is not normally cast off in its entirety at each menstrual epoch and then renovated, nor is it even disintegrated to any considerable extent, as many would have us believe.

In regard to the pathology of the endometrium, I would like to quote, in the first place, from a text-book that was written over twenty years ago by one whom I believe is as justly entitled to be called the father of gynecology as J. Marion Sims, and whose student I had the honor to be when I was an interne at the Women's Hospital in the state of New York, Dr. T. Addis Emmet:

> It is all important in this relation to understand the difference between passive congestion, which is generally venous, and inflammation, which begins as a stasis in the arterial capillaries. These terms are usually regarded as synonymous, but as erroneously as many others are which are used in uterine terminology. Inflammation always involves an infiltration of cellular elements into the parts, or a multiplica-

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

> tion of those already there; and this product may be recognized by an almost superficial inspection if it has not been absorbed. But we look in vain, after death, for any evidence of metritis or endometritis, or for ulceration of the cervix, as it is termed, for neither of the conditions so-called is inflammatory. On the contrary, in the conditions in which these are supposed to exist, the tissues are blanched, the blood from the capillaries having passed into the larger vessels as the heart failed to keep up the supply; and there is to be detected neither loss of tissue on the surface of the mucous membrane beyond the epithelium, if even to that extent, nor any hyperplasia in the organ itself. Inflammation, strictly speaking, can exist only in an acute form, although its products may remain for an indefinite period. Therefore, the term chronic inflammation applied to the uterus is a misnomer, and only serves to give erroneous impressions of the pathology and treatment of uterine diseases. Inflammation of the uterine body never occurs except after parturition, and those conditions which are commonly held to be the direct results of inflammation are due wholly to obstructed circulation in the organ, caused by pathologic processes in the cervix and neighboring parts. In this way the formation of flexures, many displacements, and the so-called uterine hyperplasias, with their attendant leucorrhea, are to be accounted for.
>
> We shall have made a great advance in solving the problem as to the true pathology of many supposed uterine diseases when we seek for the cause outside the uterine limits.

In the second place, I will quote from a more modern author and at the same time one who is as well known, Dr. Howard Kelly:

> Acute endometritis is generally found in acute septic processes involving the entire genital tract, but on account of the predominating symptoms of the other organs it is usually overlooked. Under any circumstances it is a rare affection.
>
> Chronic endometritis is also rather rare. The prevailing habit of describing all scrapings, particularly because of their abundance in some cases, as examples of endometritis, is greatly to be deplored. It interferes with our getting any satisfactory idea as to the frequency of the real affection and tends to encourage unnecessary operating. The so-called "fungoid endometritis" is not a pathologic entity at all, and the name ought to be expunged from gynecologic works.
>
> Chronic endometritis is oftenest associated with old cases of pyosalpinx; it is rarely ever found in the ordinary scrapings. The slight liability of the uterine mucosa to this affection may be ascribed to two factors: In the first place, the tendency of pus-containing tubes is to complete closure at the uterine end, and so shutting off one avenue of infection, and, in the second place, the form and position of the uterine canal is such as to afford good drainage.

After quoting two such eminent authorities on this subject, it leaves but little for me to say; but I can not help but add that a true endometritis can only exist as the result of a direct irritant to that structure, be it in the form of a microbic invasion or otherwise, conditions that rarely occur. The endometrium, owing to its intimate relations with the uterus, already alluded to, naturally will partake of any of its circulatory disturbances. The circulation of the uterus may have been interfered with, the uterus may be infected, inflammatory conditions of the appendages may affect it, it may be the home of new growths, and in all these conditions the endometrium will surely be affected, but does not represent a diseased condition by itself.

As to treatment, there is only one successful one, and that is the removal of the cause when it can be discovered. Local measures aimed at the endometrium proper will be of no avail. Scraping out parts of the endometrium with a curette will not cure a lacerated cervix, a subinvolution, a displacement, pus-tubes, a new growth, an infection nor even a virginal or senile endometritis, whatever these terms may mean.

I have said little or nothing about a condition which, perhaps, some of you may have in mind, and that is gonorrheal endometritis, and it is because I am in doubt as to the existence of a gonorrheal infection of the endometrium, on account of the lack of evidence. One of the text-books from which I quoted my varieties of endometritis assures us that such a condition is very common; that it frequently attacks the muscular structure of the uterus, and even produces abscess of the uterine walls. How any one can make such a statement I do not know. That the gonococcus frequently attacks the cervical endometrium is a well-established fact, but, as I have already said, I am only speaking of the endometrium of the body of the uterus, I will admit that this is a disputed point.

I have only attempted to treat this subject in a very general way, as it would be impossible to take up and to discuss each and every author's point of view and his reasons for classifying endometritis as he does, nor do I wish to deny him his right to his individual opinion. When it comes to teaching students, however, it seems to me that they have a right to the knowledge of the facts in the case, and that there should be some concerted effort on the part of teachers to learn something of the true etiology and pathology of endometritis, the knowledge alone of which will lead to a rational treatment of this condition.

DISCUSSION.

Dr. H. O. Marcy, Boston said that the utricular glands of the uterus have a function far greater than is usually supposed, and less damage is done in their curettement than would be the case were it not for the fact that their deeper portions are deeply imbedded in the connective tissue layers of the uterus. But for that curetting would do irreparable damage. Shedding of the uterine mucosa is a sort of cleaning house for the little tenant that Nature desires, and a great deal of damage and very little good may be done if physicians do not understand the physiology of these glands.

Dr. Ernest F. Tucker said that he thinks that gynecologists are not so well versed in anatomy, physiology and pathology as they should be. Most of our text-books are written by clinicians, and it throws discredit on gynecology to have such a variety of diseases mentioned in the text-books used in the colleges. This state of affairs ought not to exist, and Dr. Tucker said that he desired to impress teachers with the necessity of taking up this matter.

TRANSPLANTATION OF BONE FOR THE RELIEF OF SADDLE-NOSE.

WITH REPORT OF ONE CASE.*

CULLEN F. WELTY, M.D.,
Assistant in Charge of Otology, Postgraduate Department, University of California (San Francisco Polyclinic), Aural Surgeon City and County Hospital.
SAN FRANCISCO.

In 1900, Gersuny of Vienna reported the use of paraffin injection for the relief of deformity. Since then medical literature has been full of reports of the brilliant results attained by this procedure. The original method has been modified somewhat; we have learned by experience that all cases are not amenable to this form of treatment; we have also learned that serious complications sometimes follow its use.

In this paper I wish to make a comparison and to draw conclusions between paraffin injections and plastic surgery for the relief of saddle-nose.

The selection of cases is of the greatest importance if good cosmetic effect are to follow paraffin injections. I can not do better than to repeat what Paget[1] says:

---

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

> It is important that the skin of the nose be free, loose, soft, healthy and abundant, so that you can raise it a full fold between your finger and thumb. If it is rigid, set and strained, so that you can not well raise it off the frame of the nose, you can hardly raise it or keep it raised with paraffin.

Especially if the skin be scarred, and thin, and adherent, stuck down here and there to what is left of the deeper structures, the case is wholly unfavorable and almost impracticable, as everything depends on the state of the skin. It is all a matter of tension; if the skin be stiff and not loose, it will not submit to be raised. It will retaliate on the paraffin. The freeing of adhesions by the use of a tenotomy knife has not been sufficiently satisfactory to be recommended.

The complications that may arise from the use of paraffin injections are many. They have been enumerated so many times that I will not go over the list, but will speak of the more important ones later.

Some of the complications may be eliminated by carrying out in detail every feature of the operation. As is said for plastic surgery, the execution of the minutiæ is that which makes a good or bad result.

Downie[2] performed an experiment that is interesting. He injected paraffin deep into the breast of a patient, in whom the breast was to be removed a week later. Careful sections were made; the paraffin appeared almost entirely in the deeper portions of the subcutaneous fat, distributed in blocks of varying size, the largest being about that of a pea. The masses are distinctly lobulated, more irregular, with rounded processes occupying apparently in every case a position between collections of adipose tissue which had been displaced by them.

It is inferred that the paraffin had made its way along the lines of connective tissue trabeculæ between the fat-containing cells. He further says that, from the fact that the infiltration of the paraffin is definite and tolerably intimate, it is difficult to believe that its position would subsequently alter to any extent, although its absorption is possible. He also injected molten paraffin into various parts of artificially warmed cadaver; in each instance the paraffin solidified in mass deep in either the cellular or the muscular tissue; an altogether different result to that obtained when the paraffin was injected into the living subject.

These experiments are worthy of more careful investigation. Downie says that the paraffin may be absorbed; if it is absorbed, how does this come about? Is it digested, so to speak, or is it carried off in smaller particles, which may or may not produce trouble, depending largely on the tissue involved and the amount that happens to accumulate in a given place. I am inclined to the former theory and believe that the paraffin is digested and absorbed. If the paraffin were carried in mass, we would sometimes have emboli following. In all the cases with which I am familiar, the embolus followed almost immediately. This is a very important point to determine, because it would aid us materially in learning something definite of the ultimate outcome of paraffin injections.

SUMMARY OF CASES IN THE LITERATURE.

A. W. Morton[3] made some valuable observations with paraffin at 109 F. At the end of one month, globules of paraffin were surrounded by a capsule of embryonic tissue; at the end of the second month, connective tissue had increased and new blood vessels were permeating the mass. The masses of paraffin had grown smaller and were surrounded by embryonic tissue which had penetrated the paraffin. At the end of the third month, there was a vast increase of new tissue, connective, fibrous and embryonic, with a decrease of the paraffin. At the end of the fourth month, the spaces that were filled with paraffin were entirely filled by embryonic tissue.

If these findings can be relied on, they are very important, as they add to definite knowledge, at the same time producing just the condition we would most wish for. Morton does not offer any theory as to how and why the paraffin disappears or why the new tissue is produced. If the theory of digestion or chemical change is correct, there is sufficient cause for the formation of the new tissue.

Bradley[4] reports a case in which paraffin remained as a foreign body after traveling in the tissue and gave rise to deformity. On operation he found a large fibrinous cicatrix, but no paraffin.

Smurthwaite[5] reports the results of experiments on dogs with the injection of paraffin. Two months following the injection, no paraffin could be found; fibrous connective tissue was present in the injected area.

Comstock, of Minnesota, in some experiments on rabbits, found that the danger of embolism was greater as the melting point was lower. On the other hand, Eckstein's paraffin with a melting point of 136 F. causes a good deal of local inflammation, but no cases of embolism have been reported following his method. It is said that if embolism were to follow this method, it would probably be due to the heat.

The complications that are more likely to follow hot injections are abscess and glazing and thickening of the skin. It is generally conceded that the greatest danger in the use of paraffin injections is from emboli, but the mode of their production is not fully appreciated. It is a fact that most of the cases of embolism have occurred when the melting point of the paraffin was below 110 F. On the other hand, it will be interesting to note the frequency with which embolism follows the injection of mercurial preparations suspended in liquid oil.

Hartung[6] reports one case in 8,000 intermuscular injections. Moeller[7] observed embolism 28 times in 3,835 cases; he then changed from intermuscular to subcutaneous injections and found no embolus in 240 injections. Neisser[8] had one embolus in 900 cases, and Epstein had seven in 8,292 subcutaneous injections. Paget says that 1 per cent. of all cases of paraffin injection are followed by embolism. Pfannenstell[9] reports a case of pulmonary embolism; the paraffin was at temperature of 115 F. Leiser[10] reports a case of thrombosis of the ophthalmic vein. Hurd and Hulden[11] report an embolism of the central artery of the retina following the injection of paraffin at 114 F. Paget[12] reports four cases in which paraffin injections were followed by chronic inflammatory thickening; in three of the four cases it was necessary to undo what had been done at the cost of a scar. Spicer[13] reports a case of paraffin getting into the eyelids. Smith[14] reports two cases of paraffin being carried to the inner canthus of the eye and one in which it was carried to the nasal cavity.

Brady,[15] after the lapse of six months, had to do a secondary operation on account of the paraffin being misplaced. On cutting down he found a mass of newly-formed connective tissue, fibrocartilaginous in consistency. Barker[16] reports a fatal case in which the melting point of the paraffin was below 110 F. M. Lejaris[17] reports a case in which, three months after a paraffin injection, there was a rapidly-developing swelling of the nose, the upper eyelids, and the left under lid. By making small incisions, minute particles of paraffin were removed. The swelling recurred again and it was necessary to remove small particles. In addition to these cases, I have collected from unofficial sources one case of blindness in both eyes and four cases of blindness in one eye.

In Paget's last report of 70 cases he states that in some cases the result is fairly satisfactory and in some he has failed to do much good. In a few cases he is sorry he ever meddled. He concludes his article by saying that plastic surgery would have been better in some of the cases.

CONCLUSIONS FROM STUDY OF REPORTED CASES.

1. From the foregoing complications, I do not think we are justified in assuming the risk of possible blindness for the correction of nasal deformities.

2. Plastic surgery should be recommended when possible because of the foregoing complications.

3. If paraffin injections are used at all, the cases should be selected, the paraffin should have a melting point above 115 F., and a screw-piston syringe, as recommended by Smith, should be used, so that by each complete turn of the piston a definite quantity will be introduced.

4. We do not know positively what becomes of the paraffin, but in the greatest number of experiments it has disappeared, leaving connective tissue. It is my notion that the development of the new tissue is due to a ferment that destroys the paraffin and produces new connective tissue.

5. I am satisfied that only a small number of the accidents have been reported that have followed the use of paraffin, as I am familiar with two cases in my own city; in one there was complete blindness in one eye; in the other partial blindness of one eye.

PLASTIC SURGERY.[18]

The operation for saddle-nose has a twofold purpose in view: Restoration of the bridge of the nose and the lowering of the cartilaginous part of the nose. According to König, the operation consists of lowering the tip of the nose by a transverse incision at the deepest part of the depression and filling in the defect by a flap from the forehead that carries with it the outer table of bone. This is afterwards covered by a larger flap, also taken from the forehead. Israel has modified this operation, improving the cosmetic effect. He takes a flap of skin and bone from the forehead with a narrow pedicle. Secondary quadrangular flaps are formed from the skin that has been freely loosened from the nose. Helferich has modified König's operation in a similar way. I consider the operation as practiced by Schimmelbusch the best of all the various modifications of König's operation. The frontal flap is cut so that the end is very broad, containing a plate of bone wider than it is long. The narrow pedicle consists of skin only; the large defect in the forehead can be remedied by the displacement of a large curved flap from the scalp. The flap of skin and bone is not transplanted at once into its new place, but is covered with gauze and held in a horizontal position by means of adhesive plaster for several weeks until it granulates well, giving plenty of time for necrotic pieces to be cast off and for the periosteum and bone to be firmly united. The operation is completed by freshening the edges of the flap and removing the granulations. The bony plate is sawed through lengthwise exactly along the middle, so that it can be set up like the ridge of a roof, with its skin surface internally; so shaped it is transplanted into the defect. The latter is formed by splitting the nose in its entire length and freeing down to the entire pyriform aperture. The connections of the soft parts with the bone are severed and the skin is dissected off to the sides. The old nasal skin, separated from the sides, covers only a part of the new bridge at its base. After about three weeks, the pedicle is severed and spread out over the freshened region of the glabella so that it lies in its original position. After several subsequent operations the skin may be gradually drawn over the newly-formed frame so that eventually only linear scars remain. Excellent and permanent results have been obtained from these various modifications of König's operation. The one just described is the most difficult and the most extensive. When we consider, however, that only a linear scar remains on the forehead, and that by replacing the pedicle a normal shape is given to the root of the nose and the glabella, we are justified in this procedure.

After it was found that the displaced bone formed a satisfactory and permanent support for the bridge of the nose, its transplantation in a more simple way was considered, because of the bad cosmetic effects from some of the plastic operations. Israel transplanted a piece of bone from the crest of the tibia. He freed the soft parts of the nose by a longitudinal incision and placed the bone under the skin, which he undermined from the edges of the wound. He has repeatedly succeeded in bringing about a good cosmetic effect in this way. De Ruyter and others have employed decalcified pieces of bone, platinum and silver, but not satisfactorily.

Wier[19] describes an operation in which he used the breast bone of a duck, making three incisions starting from the nasal bones, one on either side of the nose down to the alæ nasi; the third down the center. The bone remained in for three weeks, when one end came through the inside of the nose. One-half was removed and later the other, which he claims was disturbed by the removal of the first part. He says he will try it again.

Grafting of bones from other individuals has been practiced by Macewen and Poncet. I can not find a description of it in the literature. Booth[20] describes a superficial operation for saddle-nose of traumatic or congenital origin. He makes a linear incision to the tip of the nose, elevating the nasal bones and then separating the tissue on either side to a point corresponding to the compressor muscle. With catgut he gathers up the tissue, crossing the bridge; he carries out the same procedure on the other side. Tension on the suture will fill in the depression; the outer wound is closed by subcutaneous sutures. It seems to me that this is a very simple operation and likely to yield good results in selected cases.

Berens,[21] in a very recent publication, describes in detail how he has overcome saddle-nose of traumatic or congenital origin by loosening the nasal bones and fracturing the septum in various directions, raising the depression and holding it in place by means of splints. I can not well understand how this can be done satisfactorily, as in traumatic or congenital conditions the bones and cartilage have assumed such position that when fractured and elevated into the new position to overcome the deformity they will not maintain the extra weight put on them, and it would be very hard to put a tampon so tightly that it would maintain this elevation. If this can be accomplished, however, it is probably the best of all the operations for saddle-nose of traumatic or congenital origin.

CONCLUSIONS IN REGARD TO PLASTIC SURGERY.

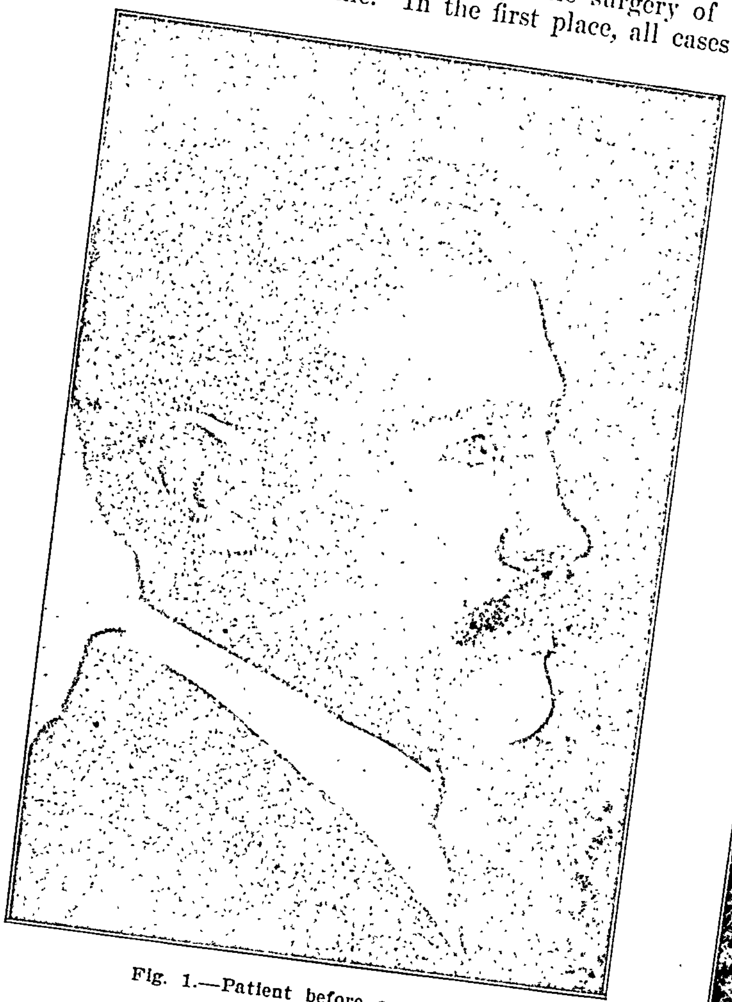

Fig. 1.—Patient before operation.

The conclusions in regard to plastic surgery of the nose are hard to define. In the first place, all cases of saddle-nose can be corrected by bone implantation, the cosmetic effect depending somewhat on the condition present prior to operation. Second, cases of traumatic or congenital origin are by natural selection more amenable to this form of treatment than cases that have an entire destruction of the bony and cartilaginous septum. In case of failure by bone implantation, one of the various modifications of König's operation may be tried; especially that of Schimmelbusch, as here described. Third, there are no serious complications, the cosmetic effect depending largely on the operating surgeon.

The deductions that must be drawn from the various conclusions lead one unhesitatingly to decide in favor of plastic surgery rather than paraffin injections. The production of new tissue by paraffin injections to overcome a deformity is almost ideal, but there is the uncertainty of possible loss of life or of vision and other minor complications, while with plastic surgery the surgeon works on better established principles.

Patient.—Male, aged 27, woodsman by occupation.

History.—The patient had a perfectly straight nose prior to an accident which happened two years ago, the limb of a falling tree striking him across the nose. The bridge of the nose was broken, producing the characteristic deformity. The patient had considerable hemorrhage from the nose for several days, and could not breathe through the nose for four weeks. The camp surgeon could not do anything for him, so after about two years he presented himself at the San Francisco Polyclinic.

Examination.—It was found that the injury was confined entirely to the anterior part of the cartilaginous septum, with a possible severing of the union of the nasal bones. The cartilage was fractured in such a way that either side which formed the support for the bridge of the nose turned into the nasal cavities, producing more or less obstruction.

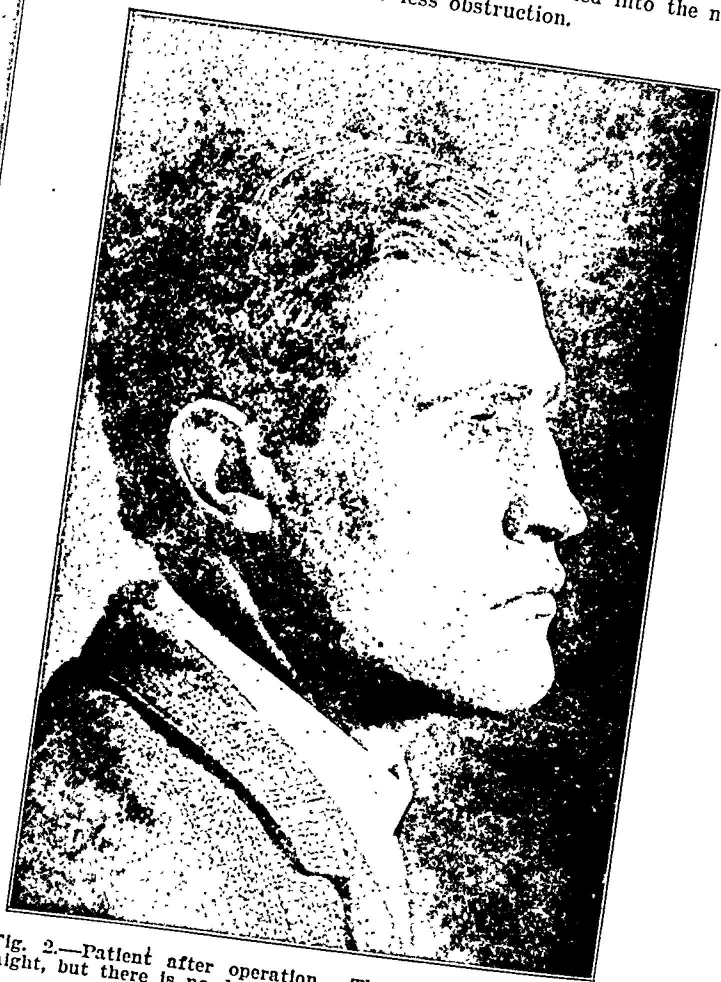

Fig. 2.—Patient after operation. The nose is not absolutely straight, but there is no deformity.

Operation.—This obstruction was first corrected, and then the operation was done for the transplantation of bone. The field of the two incisions was scrupulously cleaned 24 hours before operation, and a bi-chlorid of mercury dressing applied. An incision starting just below the union of the nasal bones was carried well into the tip of the nose, cutting down to the cartilage proper, separating the perichondrium in the hope that the implanted bone would form union at this place. At either end of the incision, the skin and fascia were undermined so that the bone could not be displaced. The skin and fascia from the sides were likewise dissected loose as these tissues were drawn tight over the bridge. This was done to lessen the tension on the implanted bone, as well as to assist in restoring the bridge of the nose. At this point I proceeded to remove the piece of bone from the crest of the tibia. The piece removed was about two inches long and the thickness of half a leadpencil. With this bone I removed more than enough periosteum to cover it, trimmed the edges with a pair of scissors, and placed it in a normal salt solution. Uncovering the wound in the nose, I adapted the bone to the cavity that had been made for it, and closed the wound by deep sutures. The periosteum of the tibia was sutured with cat-gut, and the skin with silk. There was not a drop of pus from either wound.

Remarks.—Before doing this operation I looked up some of the literature on plastic surgery of the nose, and concluded I would try to do this operation by a simpler method. I found that the implantation of bone from the lower animals had not been entirely satisfactory, and I decided to use a piece of bone from the patient himself, and the most desirable was that of the spine of the tibia. At the end of five weeks the bone was in place, and I intended to report the case as an original operation, but in the review of additional literature I found that my identical operation had been satisfactorily done before. It is now five months since the operation, and I have every reason to believe that the bone will remain in place permanently, provided it has sufficient nourishment; if not, it will atrophy with the possible formation of new connective tissue, which would be more ideal than at present. As stated before, I had hoped the bone would unite, but it did not. Since then it has become apparent that had it united a fracture would have followed the slightest traumatism.

The photographs show that there is not quite sufficient elevation to make an absolutely straight nose. Had the bone been larger, this would have been entirely overcome. In all cases of saddle-nose there is an apparent widening and in some instances a real widening of the base of the nose. This is overcome by lifting the bridge with a lowering of the tip; and this can be brought about by the length and thickness of the bone implanted.

This Israel modification of König's operation is in its infancy. With good surgical principles adapted to it, the use of bone implantation for the correction of saddle-nose will surpass all other methods of treatment for this condition.

606 Sutter Street.

DISCUSSION.

Dr. W. S. Anderson, Detroit, said that when paraffin injection was first advocated he took the matter up, thinking possibly that it would be found satisfactory in the correction of many deformities of the nose. When he commenced his work there was little literature on the subject and he did considerable experimenting. He very soon found its limitations. The procedure seemed very simple, but the technic he found difficult and the results not altogether satisfactory. In saddle noses the skin frequently is not freely movable, so in many cases the paraffin will go everywhere except where it is wanted. Nevertheless, in a few cases Dr. Anderson got very good results, and in no case did he have a result that was positively bad; he did not make anyone worse. Since reading of the cases of blindness following this apparently simple operation he has hesitated to use the method. Such a result would be a very serious thing for the patient. Since this method is used for the cosmetic effect rather than as a lifesaving procedure, physicians ought not to take any risk. The first case in which he used it was that of a woman who had had for many years a typical saddle nose as the result of syphilitic necrosis. The result was very satisfactory, indeed. In that case the paraffin was used three or four years ago. He used it in another case in which a man was crushed under a beam and the nose was flattened out. A general surgeon did something toward repair, and later Dr. Anderson operated under a general anesthetic. He refractured the nose until it was very movable and raised up the whole organ. He used a urethral steel sound to raise it up and got very good results. He then did several operations under cocain to give better breathing capacity and finally injected the paraffin. This was done in November, and during the first cold spell the patient came in and said that his nose felt all the time as if it had "a chunk of ice on it." The paraffin was outlined in white, due to imperfect circulation. These symptoms all passed away after a few months when the circulation was reestablished.

Dr. Otto T. Freer, Chicago, said that he has refractured noses that have been broken some two or three weeks before the resetting and in which the fragments have reunited in a faulty position, and he has seldom found the releasing of the broken pieces or their molding into the desired form difficult after this comparatively short interval. He has used the steel sound, as Dr. Anderson describes, in lifting up the bridge of the nose. The result, nevertheless, somewhat disappointed him, for in spite of tamponing the nose often would not stay in shape and some deformity would recur. Dr. Freer described briefly Dr. Robertson's method of operating in cases in which the nasal bones are driven backward between the nasal processes of the superior maxillary bone. A vertical incision is made in the center of the nasal bridge and the nasal bones are chiseled loose from the nasal processes of the frontal bone and lifted up, after the septum has been incised. The nasal bones are then fastened to the frontal bones with a wire attached to the frontal bone above the origin of the nasal bones. The wire is passed under the nasal bones and by tightening it these bones are lifted up into place; Dr. Robertson leaves the wire in place.

Dr. H. Foster, Kansas City, Mo., stated that when paraffin first came into use for the correction of deformity he tried it, using the hard paraffin boiling at about 150 F. He had difficulty in getting the paraffin into the tissues. He then read an article by Smith recommending melting paraffin at 110 F., and since using this he has had no difficulty. He believes that bad results are often due to the physician not being aseptic in the operation. While the rhinologist need not go into the details of asepsis like the general surgeon, they should boil the instruments and be as careful as possible in operations on the nose. In ten or fifteen cases Dr. Foster has had excellent results from the use of paraffin with a melting point at about 115 F. Dr. Roe of Rochester has frequently elevated the nose with wires, etc., with most excellent results. In some cases paraffin is ideal. In many cases of saddle nose from specific causes it is useful. It is better to use too little than too much paraffin. Physicians certainly must take some risk in these operations. Some objection could be raised to almost any operation. Dr. Foster declared that it is puzzling to know how paraffin may cause blindness. He has only seen the account of two cases of blindness attributed to paraffin in the records he has looked up. The physician should be careful in his technic; with absolute cleanliness this is an ideal operation. Many of these patients have cicatrices. The point of the syringe should not be introduced too deeply, and then by holding the finger at the inner canthus of the eye the paraffin is not likely to get into the inner canthus.

Dr. W. W. Pennell, Mount Vernon, Ohio, said that he treated a broken nose about six months ago. A man was skating on roller skates and went against a pillar and smashed his nose. Dr. Pennell replaced the bones, put in a rubber tube on either side and above that a smaller tube, which he kept in for a couple of weeks, replacing them from time to time. The result has been a very good nose without any particular deformity.

Dr. Robert C. Myles, New York, said that paraffin should always be injected cold. Formerly it was injected warm, but this has been abandoned because, in cooling, melted paraffin becomes hard in the syringe at the circumference, while it remains soft and warm in the center. Anyone who has had experience with warm pariffin knows how readily it diffuses. It is doubtful whether any difficulty would be experienced by the injection of small quantities of hard paraffin, 110 degrees or over, into the tissues, say three injections to a moderate saddle-back nose. Dr. Myles said that the injection of large quantities of warm paraffin has probably been responsible for the injuries to the eye, brain, kidneys and other parts of the body.

Dr. Cullen F. Welty said that probably Dr. Roe has done more plastic surgery of the nose than any one in the United States. He has good results. The descriptions of his operations are complicated and sometimes hard to follow. Dr. Welty repeated that so long as there is danger of producing an embolism with loss of vision and possibly life, physicians are not justified in using this procedure for the correction of a deformity. He is thoroughly convinced that many of the unsuccessful cases have not been reported. As soon as a paraffin is obtained that will not cause complications there will be an ideal condition both from a pathologic standpoint and from that of cosmetic effect.

THE DIAGNOSIS OF INTRACRANIAL COMPLICATIONS OF SUPPURATIVE EAR DISEASE.*

JOHN F. BARNHILL, M.D.
INDIANAPOLIS.

As a preface to the body of the paper, the following brief statistics on the subject may be quoted:

> Hassler states that of 81,684 ear cases treated there were 116 deaths due to intracranial extension. Of these 48 died of sinus thrombosis, 28 of cerebral abscess and 40 of meningitis.
>
> Köerner reports that in 115 necropsies after death from ear extension, 41 died from sinus thrombosis, 43 from brain abscess and 31 from meningitis.
>
> In an exhaustive article on the statistics of this subject, Pitt reports that of 9,000 autopsies made in the hospitals of London, the records representing the consecutive ones, and therefore was for deaths from all diseases, just as they naturally occurred, 57 were due to suppurations in the temporal bone, or one such death in every 158 running hospital cases, distributed as follows: 48 died of sinus thrombosis, 28 died of cerebral abscess, 40 died of meningitis.
>
> Köerner of Rostock, who has compiled most extensive statistics, shows that more than six of every 1,000 deaths from ear diseases are the result of brain abscess.

This frequency of otitic brain abscess and sinus thrombosis justifies the presentation of the main features indicative of the presence of such complication. The symptoms of intracranial involvement are so obscure throughout the earlier, and often the greater, part of their course as to remain entirely unsuspected by the attendant until a time when the extension is so great as to render the help of the physician of no avail; or what is equally unfortunate, the symptoms representing the intracranial involvement may be entirely mistaken for other ailments, and the serious nature of the trouble not comprehended until too late to be of any service to the patient. In view of the fact that, when untreated, infection of the cerebral contents proves almost without exception fatal, but that when early recognition of the invasion is made and prompt surgical measures taken for relief, about half of all cases promptly and satisfactorily recover, no pains should be spared in any suspected case to investigate and interpret every symptom at its earliest development, and to properly record the same, to the end that when sufficient evidence is present to justify it, surgical measures may not be delayed.

The latest pathology of brain and sinus infection points clearly to the fact that the entrance of the virus into the cranial cavity is through some one of the several open sinuses which practically surround the base of the brain, viz., the mastoid antra, middle ears, ethmoidal cells, frontal sinuses, antra of Highmore, and sphenoidal sinuses. Those who treat the diseases of the upper air tract find that the above-mentioned cavities are suppurating with great frequency, and often their mucosæ are polypoid; the bony walls are also often denuded of their mucous lining, and not infrequently areas of bony necrosis are found connecting a cavity directly with the cranial structures, thus permitting the free entrance of septic sinus contents directly into the cranium.

In the diagnosis, then, of any intracranial complication, the previous and present history of the case as concerns these open sinuses becomes of the utmost importance, since practically all statistics agree that suppuration in these localities has been found in the majority of all autopsies in which brain abscess, sinus thrombosis and meningitis have been found. Nor is it necessary that the patient give a present history of suppuration, because, and especially is this true as pertains to the ear, the statement may be made by the patient or his friends that, whereas there was once a discharge, lately the suppuration has apparently wholly ceased; that, therefore, no thought of connecting the former running ear with the present trouble has been entertained, and can only be found out by careful questioning and thorough examination of the parts. I lay great stress on this fact of the denial of ear discharge, because such denial was made in three cases of brain abscess which I have seen, in which operation proved the presence of chronic aural suppuration, necrosis and cholesteatoma. In these cases the pathologic conditions present were not productive of large amounts of pus, and the trivial quantity appearing in the external auditory meatus was readily dried into crusts which were easily mistaken for hardened ear wax. It should, therefore, be stated that no diagnosis should ever be regarded entirely satisfactory that does not include a thorough inspection of all the sinuses, and especially those of the ear. Since the symptoms of the two principal infective diseases under consideration vary very greatly, each will be considered by itself. It should be known that the symptoms of meningitis may complicate either those of brain abscess or sinus thrombosis, and so complicate and mask the real trouble as to render exact diagnosis difficult or impossible. It is also possible in any case that serous accumulations due to tubercle or that the pressure of a brain tumor may cause localizing phenomena of such nature as to render exact diagnosis most difficult.

SINUS PHLEBITIS AND THROMBOSIS.

The cause of this ailment may be briefly stated to be an infection of the vein arising from wounds about the head and neck, deep infections of the neck, infections of the tonsils, the nasal accessory sinuses, erysipelas and suppurations in the temporal bone, which latter cause is regarded by otologists as by far the most frequent of all.

The symptoms of sinus thrombosis are, in the later stages, most pronounced and usually unmistakable, the result of the general pyemic condition of the patient at this time. It is of the utmost importance, however, to the success of the surgery of this most fatal malady that a diagnosis shall be made before the disease has so poisoned the patient as to present symptoms which would be easily understood by even the indifferent diagnostician, because early diagnosis plus competent surgical interference equals commendable results, whereas late diagnosis plus either the most skillful surgery, or no surgery, is apt to result in disaster. The early recognition of the extension of any septic condition to the intracranial structures is usually difficult, and this fact has been spoken of as the weak point in the history of intracranial disease. In the very beginning of sinus thrombosis, when the thrombus is yet incomplete, and before disintegration has set in, exact diagnosis is usually impossible. However, a discharging ear can be found in nearly every case, and, when present, there has almost certainly been a complicating mastoiditis with its well-known symptoms. There may be suspicions of chilliness or even rigor, together with moderate rise of temperature, pain and tenderness, but all these could be entirely accounted for by the presence of the ear and mastoid diseases. The patient appears, however, to be suffering from a more depressing ailment than mere suppurative otitis, complicated by simple mastoid inflammation, and when these latter ailments are and have been persistently and incurably present, exploration of the mastoid is entirely justified, and a complete mastoid operation becomes, therefore, a diagnostic measure of first value in the earlier stages of a suspected sinus involvement. If such involvement be found not present, the operation is a prophylactic measure of greatest importance, as I have had frequent opportunity to observe in the very considerable number of cases in which, during the operation, I have found the bone carious or necrosed over the sinus, which later was covered with necrotic granulations and bathed in pus, thus rendering it certain that, without the free drainage afforded by the mastoid operation, the sinus must soon have become infected, thrombosed and putrid.

---

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

In the second stage the thrombosed sinus begins to soften and disintegrate, and septic portions are swept into the general circulation. The symptoms indicative of this fact, while more easily interpreted than those of the earlier stage, are by no means pathognomonic, and may yet be very misleading. The condition presented is one both general and local—general, due to pyemia, and local, resulting from the circulatory disturbances both inside and outside the cranium, that are incident to the blocking of so large a sinus. Headache, vomiting and dizziness are commonly found, but are such constant concomitants of brain abscess that of themselves they could scarcely be counted as valuable diagnostic aids. Outside the skull the occurrence of the following symptoms should be noted, if present, since they have valuable diagnostic bearing: swelling or edema behind the mastoid and over the entrance of the mastoid vein; swelling along the course of the internal jugular; edema of the eyelid of the same side. The fundus of the eye should be examined, but circulatory changes in the depths of the eye are by no means constant, for in 35 cases marked eye disturbances could be detected in only 9. Hansen found diagnostic evidence of lateral sinus thrombosis present in the fundus in only 3 of 8 cases. Köerner found only 1 in 5 cases. Jansen found choked disc rarely present in simple thrombosis. By far the most characteristic symptoms are the high temperature, with remissions, and the septic chills. The latter, although the most constant, are not invariably present, and Whiting records the entire absence of rigors in 18 cases, and 48 are noted as having had but one. However, there is usually at least one chill in the twenty-four hours, and this is quickly followed by a rise in temperature to 103 to 104 or even 106, the fever remitting markedly, during which time the most profuse and exhausting perspiration occurs.

All or even a majority of the above symptoms are scarcely present in any one case, but if only a few of them are noted in any patient who has a chronic discharging ear, or who has an acute discharge that has pursued a violent course with undue lack of recuperative powers, the involvement of the vein should be thought of. The most accurate observation of all symptoms should at once be instituted and recorded, to the end that an amount of information may be obtained sufficiently early on which to base a positive diagnosis before the hopeless stage of metastasis has been reached.

Diagnosis in the final stage of the disease should not be difficult, but a diagnosis made at this late period is neither commendable nor useful. Septic emboli have found lodgment in the lung, producing septic pneumonia, with its harassing dry cough and oppression in the chest; or possibly the emboli have been carried to more distant parts, resulting in multiple metastatic abscesses and death.

Sinus thrombosis may be mistaken for malaria, typhoid fever, acute tuberculosis, and in children for acute digestive disturbances. In some instances the differential diagnosis is not readily made. However, proper energy in using the diagnostic measures now at the command of the profession will seldom fail to clear up the most difficult case in ample time to permit of the successful employment of one of the most triumphant of all surgical procedures, viz., exposure of the lateral sinus and internal jugular vein throughout their courses in so far as found diseased, the removal of their septic contents, and at the same time ligating the channels of entrance for further septic material into the general circulation.

SYMPTOMS OF BRAIN ABSCESS.

The symptoms of this ailment, like those of sinus thrombosis, are preceded and nearly always accompanied by a suppurating ear. The fact that the patient and his friends may deny the presence of such a discharge should never deter the diagnostician from making the most rigid examination of the condition of the fundus of the ear and ascertaining for himself, first hand and to an exact certainty, the actual condition of the middle ear and its surrounding cells. Every means of examination known to the otologist that will help in the accuracy of this examination should be used, to the end that the information thus gained is positive, and, therefore, of first importance and greatest value in connection with other symptoms which may be present and indicative of brain abscess.

Brain abscess may result from either acute or chronic suppurative otitis, and the symptoms in this respect vary considerably. I have seen three acute cases, in all of which the ear ailment from the beginning was severe, the pain excessive and the patient unusually prostrated within a short time. In so far as was noted by careful observation, no symptom arose during the course of the otitis which could have been pathognomonically diagnostic of the occurrence of brain extension, and it was, therefore, not known how early in the history of the ear disease that the abscess of the brain began. The ear symptoms in no case showed any signs of improvement at any time, and the pain about the ear and over the temple was much worse than would usually be expected in uncomplicated ear cases. In one, the worst of the three, this pain was intense and persistent and, being unaccounted for otherwise, was attributed to suppuration in the mastoid cells, and, although there was no pain, tenderness or swelling behind the ear, the mastoid operation was performed, pus in abundance was found in the cells, and assurances given the patient that the cause of the pain had been removed. Such promise was without sufficient knowledge of the case, the pain continuing unabated. Two days later paralysis of the arm of the opposite side, vomiting, unequal pupils, subnormal temperature and unconsciousness developed with great rapidity and so markedly that the diagnosis of brain abscess was made with little difficulty and, as proven by operation, with absolute certainty.

The two other cases were less severe as to pain, mastoiditis was present in each by the tenth day, and symptoms of brain irritation and pressure followed rapidly.

Rigors were not prominent features. Moderate elevation of temperature was at first present, followed by subnormal. Likewise an accelerated pulse, which later was very slow. Headache was present in all, and in each was far forward and about the brow. Each case at some time vomited. Only one of the three had any irregularity of pupil or marked paralysis of any muscle or group of muscles. The reflexes were highly exaggerated in each. The diagnosis of brain abscess was made on the following points: (1) A case of acute otitis media suppurativa, violent in every respect. (2) The headache, one-sided and about the orbital process. (3) Subnormal temperature and pulse. (4) Exaggerated reflexes. (5) Vomiting. (6) Exploratory operation.

If the abscess is the result of chronic suppuration within the temporal bone, the primary disease may have preceded the brain abscess only a few months, or the ear may have been discharging many years. There is usually very little evidence in or about the ear itself, further than the discharge, to warn either the physician or his patient of the approach or existence of serious intracranial disease. Many recorded cases show that the patient has followed his usual occupation often up to the day, or even the hour, that he is stricken down with the severe and fatal complication. Postmortem examination has demonstrated the fact that these abscesses must have existed for a long time, their presence being absolutely unsuspected by any one. It is believed, however, that greater care as to the examination of the ear disease, and of the local and general symptoms produced by the brain extension, would have made it possible to have reached a diagnosis of the true ailment before the fatal symptoms were present and at a time when well-applied surgery would have been worth while. It is doubtful if the physician who stands idly by as the attendant of one of these cases and permits the malady to go on to a fatal issue without recognizing its nature can lay claim to better management than could the Eddyite who denies the existence of all disease.

The symptoms of brain abscess in the earlier stages are like those of sinus thrombosis in the respect that they are often very indefinite. There is, however, probably enough evidence present in the majority of cases to cause the attendant to suspect the existence of brain trouble, and, if he be alert as a diagnostician, to cause him to give the closest heed to each symptom as it develops, and to interpret and properly record the same. Hemicrania is seldom or never wanting, appearing as an early symptom and persisting throughout. It is seldom complained of over the site of the abscess, and may be quite a distance from it, as in one of my cases in whom the pain was persistent and severe over the region of the frontal sinus of the same side of the head. Such a persistent headache in connection with a foul-smelling ear, in which necrotic bone, granulations and cholesteatoma is discovered to be present, should not fail in any case to cause the medical attendant to think of brain abscess. Irritable disposition of the individual has also been noted as an early symptom, but is usually most prominently spoken of after other and graver symptoms have developed, those observing it earlier thinking little of it at the time. I believe, as an early symptom and taken in connection with those mentioned above, that it has good diagnostic value. The temperature is either normal or slightly elevated in the beginning, but as the abscess enlarges and brain pressure becomes a prominent symptom there is almost certainly a subnormal body heat, and this fact becomes sooner or later a most valuable diagnostic one.

Accompanying the subnormal temperature, the pulse is greatly slowed, running as low as 60, 50 or even 45 per minute. These circulatory and calorific disturbances may occasionally be accompanied by rigors, but while a chill may occur at some time during the disease it is certainly not to be compared in diagnostic value to that of sinus thrombosis.

Vomiting is a symptom almost certain to be noted at some time during the progress of this disease. It comes on in many cases sufficiently early to become of very great value, provided it is recognized as a symptom in connection with others occurring at the same time. It has been my privilege to be present on many occasions when the vomiting occurred, and the term "projectile," used to describe it, is not misapplied. However, in the earliest stages there may be retching and the presence of bile in such amounts as to mislead the physician into a diagnosis of intestinal or liver ailment. One such case in which the vomiting was persistent was diagnosed "irritation of the pneumogastric nerve," and this after consultation, and by medical gentlemen of good training.

The fundus of the eye furnishes evidence which, taken in connection with other symptoms, has important bearings. Such eye changes have been found in about one-half of all the brain abscesses in which careful examination was made.

PECULIAR SYMPTOMS FOLLOWING A RADICAL OPERATION.*

GEORGE F. COTT, M.D.
Clinical Professor of Otology of Buffalo University.
BUFFALO.

Patient.—Dr. N. C. H., Buffalo, N. Y., consulted me during her student years regarding a fetid discharge from the left ear. I found a large perforation in the drumhead and carious bone wherever the probe reached. She received local treatment four weeks, when the discharge stopped. After several years she called on me again, complaining of unbearable pain in the ear. She was then under the care of Dr. Buswell for myocarditis. She had a pronounced regurgitant murmur and often had severe pain in the region of the heart; this occasionally kept her awake until 4 or 5 o'clock in the morning, and when that did not trouble her the pain in the ear would take its place. I consulted Dr. Buswell and was advised that he would get her ready for operation. I put this off as long as possible, but, as the pain in the ear became unbearable, she insisted on an early operation.

The previous history of the case will give an idea of the amount of destruction which had taken place without any marked symptoms. At the age of four weeks, the patient had suppuration of the right middle ear, which continued for seven months. There was no further trouble until the age of 21, while attending lectures at the Buffalo Medical College. There had been no discharge since, but more or less constant pain. By advice of friends she consulted a prominent specialist of New York City, who saw her five times during her stay. He advised her to allow no one, under any circumstances, to operate on that ear. I knew nothing about the New York visit at the time I operated, a week later.

Operation.—On May 12 she entered the Sisters' Hospital. On account of the condition of her heart, Dr. Hoover tried to anesthetize her with nitrous oxid and oxygen, but after a half hour's trial this was abandoned and ether substituted. Dr. Buswell took charge of the anesthetic, but after another tedious trial, had to abandon it for chloroform, to which she readily responded. I then did a complete radical operation and found the mastoid cells and accessory cavity filled with granulations and débris, but no pus. The ear was then dressed and the patient put to bed. She soon regained consciousness, but had considerable pain, and at 9 p. m. was given 1/4 grain morphin hypodermically. She slept intermittently about five hours during the night, vomited green fluid at 4 in the morning, and several times during the next few days. She slept at intervals, but always complained of pain after waking.

---

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

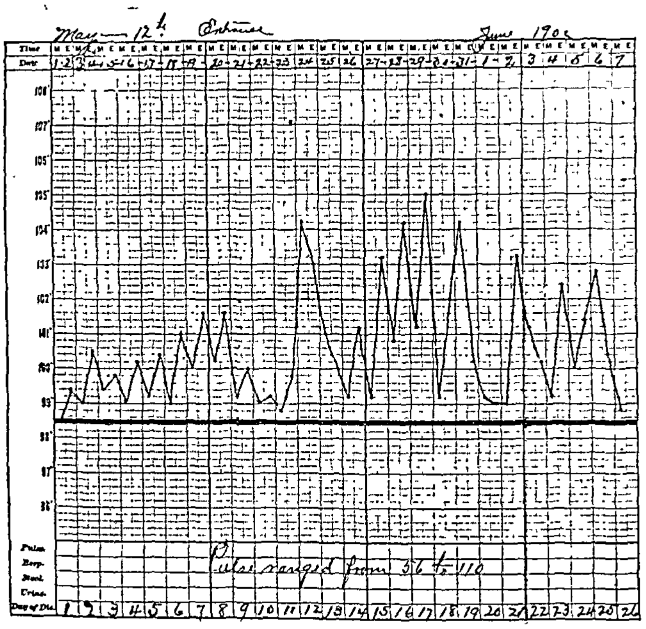
Postoperative History.—Two days after operation the dressing was changed on account of pain. The ear looked very well. The urine was examined and the specific gravity was found to be 1028, otherwise the urine was normal; indican was present. The wound was dressed again May 17 and 18; pain was constantly present.

May 18: The patient sat up forty-five minutes; she was restless the whole night following and morphin 1/6 grain was given.

May 20: Patient slept well.

May 21: Patient slept very little before 4 a. m.

May 28: A twenty-four hours' sample of urine, tested by Dr. Brown of the Sisters' Hospital, showed specific gravity 1007, indican slight, urea 59 per cent., a large number of epithelial cells, a few bacteria and pus cells; the reaction was neutral.



May 25: On account of the vacillating temperature, a blood count was made by Dr. Wixen: Leucocytes, 13,300; red corpuscles, 5,500,000.

May 24: The temperature suddenly took a jump to 104.4 and kept rising and dropping until June 1, reaching 105, May 29.

May 26: There was pain in the region of the heart; at 11 p. m. she had a slight chill and was restless all night. Twenty-four hours' sample of urine showed: Color pale, reaction neutral, appearance cloudy; specific gravity 1005, urea 29 per cent., a large number of epithelial cells and many bacteria.

Examination of the eyes by Dr. Hubbell: Fundus, both eyes, normal except perhaps abnormal fullness of central retinal veins and long branches; no optic neuritis. Pupillary reaction to light normal; vision not disturbed.

Consultation and Subsequent History.—Having decided, in consultation with Drs. Henry Buswell and Edward Meyer, that there was a sinus phlebitis with probable thrombosis, arrangements were made to operate next day, June 1. On the day before there was a slight chill and nervous twitching of the limbs. Dr. Hubbell again examined the eyes June 1. He found great fullness of the retinal veins in both eyes. On the evening of June 1, the time when we had intended to operate, the temperature did not go much above 101, then dropped to 99.4. This led us to postpone active interference for a short time. The following day the temperature jumped to 104.4, then dropped to 99. This was followed by a rise to 103.4, declining again the following day. It rose again June 4 to 102.6.

On June 3 she slept all night; on June 4 she had a slight chill; on June 5 and 6 she had pain in the region of the heart. On June 7 the temperature dropped to 98, and after that never rose higher than 100.4 except on the day she left the hospital, when it was 104. Urinalyses were frequently made.

Blood Examinations: Frequent examinations were made of the blood, the last one on June 6, the day of the final regular rise in temperature, this time by Dr. Charles S. Jewett. He found leucocytes 9,000.

DIFFERENTIAL COUNT.

	Per cent.
Small lymphocytes	5.5
Small mononuclear and transitionals	2.5
Polymorphonuclear neutrophiles	92.0
Eosinophiles	0.0
	100

While there is no numerical leucocytosis, the differential count is highly suggestive of an inflammatory reaction. The stained specimen shows no other abnormalities.

During the rise and fall of temperature, the patient's pulse varied from 56 to 110. She was markedly neurotic, which fact caused us to hesitate before exploring the sinus, and the result seemed to show the wisdom of this precaution. She was able to leave the hospital June 15, the thirty-fourth day after the operation. During the following year there were times when she suffered considerable pain in the ear, but not sufficient to call for opiates. The temperature I have never found normal; however, she has very much improved in general health. One point in this connection is of considerable interest. The doctor was perfectly apathetic regarding the outcome of the operation, knowing, with her crippled heart, the risk she was taking; in fact, rather urging us on when we contemplated opening the sinus. She has now gained in flesh, sleeps much better, and the ear is practically well.

85 N. Pearl Street.

DISCUSSION

ON PAPERS BY DRS. BARNHILL AND COTT.

Dr. **Hill Hastings**, Los Angeles, said that he has seen several cases with intracranial symptoms in which nothing was found either at operation or autopsy. In one case he did a simple mastoid operation and there developed in about a week paralysis of the external rectus of the eye on the same side as the operation. It worried him considerably because he had not heard of a similar case and had rather suspected an intracranial involvement. The patient had also a good deal of dizziness both before and after the mastoid operation, and the discharge from the middle ear continued after the operation. Those three things made Dr. Hastings suspect intracranial involvement. After three or four days he concluded to convert the mastoid operation into a radical operation, and then he found a fistula through the inner wall of the inner ear, through which pus escaped. The patient made an uneventful recovery. Dr. Hastings did not think it wise to go into the brain unless there were stronger indications. He could find nothing similar in Politzer, nor was the complication present in 300 cases that he had observed for some time. His attention was called later to an article in which a writer (Gradenigo) reported several cases of acute suppurative otitis media in which paralysis of the external rectus occurred. The paralysis passed off and the author had concluded that it was due to a localized meningitis at the tip of the petrous portion of the temporal bone, which had involved the nerve. It is an intracranial symptom that worried Dr. Hastings a great deal, since he thought possibly he had a brain abscess to deal with. He has seen several cases in children in which there were very active meningeal symptoms that passed off without serious trouble. He had one case that he practically gave up. The child had active meningitis. It could not nurse, was unconscious, had paroxysms of twitching and regular spasms. He kept the child in a mustard bath for several hours, and it subsequently recovered. Politzer mentions headache in the orbital region as a very valuable sign of abscess of the brain. His chief indications are slow pulse, yawning and increasing dizziness with headache. Dr. Hastings had one case of brain abscess in the temperosphenoidal lobe, with severe pain referred to the orbital region, which immediately subsided on cleaning out the abscess cavity. The abscess recurred after six weeks. He did not keep it open long enough and the woman was later seized with the same symptoms and the old cavity was opened up and found to be filled up again with pus. The patient complained of the same old pain in the orbital region. Those are very important symptoms. Dr. Hastings had not seen paralysis of the external rectus before. The fact that there was pus in the urine in Dr. Cott's case indicates that that may have had something to do with the irregular fever. Again, it may have been a malarial case. The fact that the sinus was not uncovered and examined makes it difficult to prove anything about it. It seems to Dr. Hastings that physicians should always look at the sinus in such cases. Almost any general surgeon would regard that as a proper procedure. If it is inflamed and there is serious doubt, it should be opened. A thrombus should not be left behind to break down and cause sepsis.

Dr. George L. Richards, Fall River, Mass., said he has had some rather unfortunate experiences with brain abscess. He does not think there are any symptoms or combinations of symptoms that are pathognomonic of brain abscess. There may even be no symptoms at all prior to the most serious manifestations. A case that came under his observation illustrates this latter point. A man of middle age, with a history of an old purulent otitis media, was admitted to the eye and ear department of a general hospital where there was no distinctively aural surgeon. The visiting surgeon ordered a mild wash with which to wash out the ear, and after a day or two, as the man was much better and the discharge practically stopped, he wished to go home. He was discharged by the interne at his own request, and left the hospital the latter part of the afternoon of the day of his discharge. He did not reach his home that night, but was found the next day at noon in a swamp, unconscious and hemiplegic. Dr. Richards was called by the surgeon, and after opening a sclerosed mastoid and finding nothing to account for the symptoms, he trephined above the ear and made the old classical operation that the surgeons do. The dura did not pulsate and an incision was made about a quarter of an inch into the brain substance and from one to two ounces of the foulest smelling pus was evacuated. There was some improvement in the general symptoms for a day or two, but death occurred on the fourth day. Dr. Richards asked how could anybody, no matter how trained as an aurist or how conversant with the symptoms of brain abscess, have made a diagnosis in such a case. Yet no doubt that abscess had been in existence for days or perhaps weeks.

Dr. C. F. Welty, San Francisco, declared that by a process of elimination with the various means at our disposal it may be possible to clear up many doubtful cases of cerebral complications. Of course there are some cases that can not be diagnosed at all; if there are, it seems to Dr. Welty more of a guess than a diagnosis based on rational conclusions. He was visiting one of the most noted ear hospitals, and making the rounds with the surgeon in charge, when he said: "Doctor, I have an intuition that this patient has a cerebellar abscess; we will operate in the morning." The patient was operated on the following morning; no abscess was found. Two days later some pus was discovered coming from a previous incision that had been made through the dura, which communicated with a large abscess cavity in the cerebrum. At the time Dr. Welty asked the professor about this intuitive feeling in this case, and his reply was that sooner or later all otologists who operate, experience the same. In this particular case there was a slight indisposition on the part of the patient; otherwise he was perfectly comfortable for a patient who had been operated on a short time previously. The question when to operate, in Dr. Welty's opinion, is much more easily decided. Practically all patients with cerebral complications die if not operated on; we also know that to decide that a case is meningitis does not make it so. Dr. Welty has seen a number of meningitis patients operated on; of course they die. He has also seen a few cases that happened to be brain abscess, and some few of these patients got well. He saw one patient get well from a meningitis, which had been diagnosed and demonstrated by lumbar puncture, and he believes that there are some eighteen on record. In cerebral complications the earlier the operation the more chance the patient has of ultimate recovery. It is a conceded fact that most of the cerebral complications come from chronic suppuration of the middle ear. Dr. Welty asked if anyone could give him any plausible reason why an ear should be allowed to discharge for years when it can be cured by radical operation and the danger of cerebral complications absolutely eliminated. He estimates that 15 per cent. of all patients with chronic suppuration of the middle ear die from cerebral complications if they are not operated on at all. This estimate is based on a series of operative cases that would have terminated fatally had the process not been interfered with.

Dr. W. S. Bryant, New York, said that Dr. Barnhill emphasized an important point, that is, that the ears should be examined periodically whether there is a discharge or not, just as careful people have their teeth examined regularly. They do not wait till they have lost their teeth before consulting their dentist. In that way a great deal of deafness and suppuration can be avoided. The patient's statement regarding discharge is often worthless. In all chronic purulent ears Dr. Bryant thinks that the mastoid antrum is involved, and the mastoid cells, and if there is any question as to any complication following this involvement, the mastoid operation is indicated. The general practitioner should be instructed so that he can recognize suppuration, at any rate, and then he can recommend the patient to go to a specialist. It is too much to expect the general practitioner to make a diagnosis of cerebral conditions that puzzle those who make a specialty of this class of work. Occasionally there is paresis of the external rectus; this may follow in chronic cases and occasionally it has been observed in acute cases. Dr. Bryant has seen it last about nine months after a radical operation was performed.

Dr. A. DeVilbiss, Toledo, Ohio, stated that in probably no other class of cases there are fewer pathognomonic symptoms indicating whether or not operation is advisable. Recently he was called as an expert witness in a case of supposed murder by a saloon man. A man staggered into the saloon and was pushed over. He was taken to the hospital. Dr. DeVilbiss was called to see the case to consider operation for a supposed fracture of the skull. Unfortunately, he got there too late; the man was already dead. He suggested a postmortem, since there would probably be a trial, and this revealed a brain abscess. Dr. DeVilbiss examined the ear and found otitis media and pus in the ear at the time, and undoubtedly the brain abscess was the result of mastoid trouble. These operations, if made by careful hands, by men who have studied the cadaver well and who have had sufficient instruction, are not very dangerous, and he thinks it is due these patients to have the operation done when there is a chronic otitis media, especially when there are symptoms of mastoid involvement.

Dr. George L. Richards, Fall River, Mass., asked whether or not the operator shall look at the sinus. When he has reached the diseased bone and all the cells have been opened, Dr. Richards believes that it is unwise and unsurgical to go further and to uncover the lateral sinus. In the more destructive suppurative conditions, especially in children, when the granulations have been cleared off with the curette or otherwise, and a sinus is found that is apparently healthy, he hesitates to open it. He used to do so a few years ago just to see if the blood would pulsate, but now he leaves the lateral sinus alone unless he has definite symptoms to lead him to open it.

Dr. Kaspar Pischel, San Francisco, called attention to lumbar puncture, which in doubtful cases may give valuable information regarding the presence of meningeal affection.

Dr. **Frank W. Hilscher**, Spokane, Wash., said that several deaths have occurred in his practice because the diagnosis was not made sufficiently early. If these cases could be recognized before it is too late, it would be a step in advance. There are many cases of brain abscess that go on for months or possibly for years without symptoms or with so few symptoms that they are not discovered. He saw a case a few years ago, in a patient who was a physician, in which there was a brain abscess that involved a large portion of the brain. A sphenoiditis and ethmoiditis had broken through into the fore-brain and the whole fore-brain was involved. The patient had been ill more or less with ill-defined symptoms, mostly pain and headache. He had not seen a rhinologist or otologist, except the very first man he went to, who recognized the trouble in the nose and insisted on operating. The physician was very much annoyed because the rhinologist seemed anxious to do surgery in his nose. He went to others, none of whom recognized the true condition, and after a lapse of about three years he fell into Dr. Hilscher's hands. The patient died while he was under observation, without an operation or anything having been done. The only symptom in that case, except headache, was a sort of mental incompetency. Another patient was in the hospital about six weeks, supposed to be suffering from typhoid fever. He had no symptom referable to the ear until two days before Dr. Hilscher saw him. He then began to have an otorrhea from the left ear. Dr. Hilscher dressed his ear in the ordinary way and it readily healed, but his temperature curve was characteristic; it had never been a typical typhoid fever curve. A short time before Dr. Hilscher saw the patient the temperature had been 104, and then it was reduced to 95 or 93. Then it rose again. That led him to suspect a thrombosis of the lateral sinus and perhaps a brain abscess; but the diagnosis was not clear, since the man had never complained of the ear before and there was no tenderness over the mastoid, and particularly since the otorrhea stopped after one or two dressings. However, because of the presence of the fever and the emaciated condition of the patient, and the fact that he could eat and drink almost nothing, Dr. Hilscher made an exploratory examination. He found the mastoid largely destroyed; lateral and sinus thrombosis, and quite a large abscess of the brain. The patient was so reduced that the operation had to be stopped before it was completed. Dr. Hilscher expected to complete the operationa at another time, but the patient never rallied sufficiently. In another case, a young man had otorrhea for a number of years, and there were no brain symptoms until suddenly one day he could no longer keep his balance. He was taken home and treated by a general practitioner for a while. A short while before he died Dr. Hilscher saw him and made a diagnosis. An operation for abscess of the cerebellum was done, but he died.

Dr. **W. W. Murphy**, Los Angeles, related the history of a case that came under his observation. The patient was a young woman from Chicago, on whom a radical operation had been done. Three subsequent operations were done, at each of which some portions of the necrotic cranium had been removed. The patient had gone to Los Angeles for her health. While there she was sleepless and had headache and some fever. She came under Dr. Murphy's observation and he called in Dr. Hastings, because of the gravity of some of the symptoms. They found a little sinus in the roof of the canal and some oozing of pus. Considering the history of the case and the number of operations the patient had undergone, they thought there was probably a brain abscess. They directed her to go back to the surgeon in Chicago who had operated before, and she did so. After the operation the surgeon wrote that there was no evidence of cerebral abscess. He had probed around as much as he thought best without finding an abscess. In a day or two Drs. Murphy and Hastings received a letter stating that the abscess had broken through, and the patient died.

Dr. **G. P. Pond**, San Francisco, said that if physicians would look more carefully at the symptoms, instead of taking the patient's word, so many of these cases would not go on to a fatal termination without the otologist knowing anything about it. For instance, in the case of the man who went out of the hospital and the next day was found in a marsh, if he had been examined more carefully some evidence of pus would probably have been found. If otologists examined the eye, looked for areas of anesthesia or changes in nerve reflexes, they might often find symptoms that would give valuable clews.

Dr. **G. A. Leland**, Boston, said that as one studies individual cases there are so many symptoms that may be obscure or left out, that it has been his experience that even the neurologists themselves who are working continually in this field, seem to be at sea. A case in point occurred at the City Hospital in Boston recently. Death suddenly came on the seventh day after exenteration for chronic suppurative ears. An eminent neurologist said it was due to cerebral hemorrhage; Dr. Leland's diagnosis was probable rupture of a latent abscess; autopsy showed encephalitis. This case, he said, calls to mind others in which the postmortem findings have thoroughly upset the diagnosis. He agreed with Dr. Barnhill that otologists should endeavor to find something more definite on this subject, and said that to this end they must work together with the neurologists and alienists, and must also attempt to induce the general practitioners to put these cases of chronic suppuration immediately into the hands of the aurist. He advised educating the people so that autopsies can be readily obtained. It is common as well as aggravating that ignorant relatives refuse an autopsy frequently for no other reason apparently than to exercise a little brief authority, or to malignantly block the doctor.

Dr. **S. L. Ledbetter**, Birmingham, Ala., said that a patient came to the hospital clinic, recently, complaining of suppurative otitis media of three weeks' duration. On operation, pus was found in the mastoid cells in the antrum, a subdural abscess in the middle fossa, and an abscess lying between the bone and the lateral sinus, so it was only a question of a short while before he would have had serious trouble. A year ago Dr. Ledbetter had a patient start out with an acute inflammation of both ears and with high temperature from the beginning. On the second day he opened both drums and the discharge lasted two or three days. He tapped the drums a second time without result. There was no further discharge. The temperature continued to go up and on the seventh day he opened the mastoid on one side and found pus all through the cells. The pus had extended to the dura. Intracranial complications, he said, are frequently found when least expected.

Dr. **Robert C. Myles**, New York, said that if all the patients who have been operated on by prominent surgeons as well as by tyros, could be collected it would be found that in many cases there was no intracranial abscess. He agreed with Dr. Leland as to the necessity of educating people to permit autopsies in these cases. Dr. Myles said that he has seen a number of cases in which autopsy proved nothing, and that if people could be educated to permit autopsies in cases in which intracranial disease had not been found in patients by the operator, it would be possible to solve many of these problems.

Dr. **John F. Barnhill** declared that anyone who attempts to look up the literature, when he has a patient for whom he is anxious to do the very best he possibly can, will be surprised to find how little of real value has been written since MacEwen's time. There are very many papers, excellent in nature, and many short reports, but there is no modern treatise on the subject that seems really helpful. Dr. Whiting, in the preface to his recent book, promises an early treatise on the subject, and Dr. Barnhill hopes it may be such as one would expect from a man of his ability and experience. No one should open the cranial cavity without the strongest diagnostic reason, because such an act must never be lightly regarded by the surgeon. If there is not present trouble which requires such an operation, it is quite possible that the operator may cause a death. Dr. Barnhill said it is always highly dangerous to open the cranial cavity; to do so unnecessarily, exposes the patient to a risk that should not be taken except in the presence of grave danger. It has been his practice, when first seeing one of these cases, unless there are symptoms present that seem to be imperative, to watch, to record the temperature and pulse carefully, and to examine all the secretions; in other words, to go into it as carefully and thoroughly as modern medicine admits. All the early symptoms must be recognized and interpreted, the dizziness, the ear that has possibly ceased to discharge, the headaches and other recorded symptoms that should not be allowed to go unnoticed. If there is a little pus at the bottom of the ear that smells badly; if the patient has a headache on the same side of the head, which may be over the eye; if he has vomited and had restless nights, then the case should be observed most carefully, and the observations recorded and weighed before the cranium is opened. The experience of all men, whose experience justifies their speaking and writing, is the same, viz., that there are cases that seem to be symptomless. Dr. Barnhill asked if they are not symptomless only because physicians do not recognize the symptoms. It seems almost inconceivable that a four-ounce abscess may be present in the brain without symptoms. Frequently, it seems, the patient becomes accustomed to a certain amount of pain so that he no longer complains. Some individuals will tolerate, for instance, a tack in the boot half an inch long without complaining, or an individual will long endure an ulcerated tooth without complaint. Such a person may have symptoms of abscess of which he has ceased to complain. He recalled the case of a boy 8 years old in whom an operation evacuated at least four ounces of foul-smelling pus from the tempero-sphenoidal lobe. An examination of the limiting membrane of the abscess proved it to be of great thickness, and therefore that the suppuration was of long duration. This boy had been in school making good grades almost up to the time of the operation. His mentality had been unusually keen, and until a few days before the operation little complaint had been made further than that there was a discharging ear. Careful inquiry, however, elicited the statement that at times the patient had been dizzy, had suffered from one-sided headache and had vomited. Such attacks had readily subsided, and were attributed to derangement of the digestion. The presence of so much pus for so long a time, and with so few noticeable symptoms seems to Dr. Barnhill remarkable, and he believes that in this, as in all such cases, there are present, possibly from the beginning, more indications of the disease than are usually noticed by those in attendance. The otologist who is in a position to know the lurking dangers that are hidden in the suppurating sinuses that lie about the base of the brain on all proper occasions, should emphasize the importance of watchfulness during such ailment that graver symptoms may be earlier recognized. He does not deem it wise to operate for intracranial disease without the advice of a skilled neurologist, who is better able, in most instances, to interpret more accurately the reflexes that are present and thus be of very practical aid in locating the seat of the disease in the brain. It has been said that the neurologist has made so many mistakes as to the presence and location of the disease that his advice has proved of little assistance, but Dr. Barnhill has found quite the opposite, and will continue to avail himself of the neurologist's skillful assistance in such cases. Whether or not the surgeon should explore the lateral sinus in a case in which the contents of this channel are suspected to be infected, is one which should be given the most careful consideration in any case, and, in his opinion, unless symptoms be present that are quite indicative of the presence of such trouble, the sinus should not be opened, because if not diseased, such surgical procedure would add unnecessarily to the dangers of the case, since in entering the sinus the operator must go through a wound that is infected, and although every antiseptic precaution be taken, infection of some part of the sinus contents is probable; indeed, this unfortunate occurrence has been several times reported.

Dr. George F. Cott said that the cases referred to in which at operation nothing was found, possibly were due to uremia or something else. He thinks that they have occurred invariably in the practice of general surgeons and not in that of otologists. In 50 cases Dr. Cott has opened the skull ten times. When it comes to a question of trouble caused by the ear, and the otologist is in doubt, it is a good thing to call in the neurologist. Brain abscess may be present months or even years without symptoms. In one case, in which he did a radical operation, he found a sinus leading into the brain, he slit open the brain one-half inch and curetted, and the patient made a good recovery. Seven months afterward Dr. Cott found a large brain abscess, from which the patient, a woman, again apparently recovered; a few months later it again occurred and she died. Apparently she had no symptoms of brain abscess. These symptoms followed a radical operation. One should not hesitate to open the skull when there is some reason for doing so. Within a very few months Dr. Cott has had to operate on a patient who was treated for six weeks for typhoid fever. There was thrombus from the torcular to the bulb and an epidural abscess; the boy died. There are many cases due to irritation of the dura, pachymeningitis or adhesive inflammation between the skull and dura. There is practically no danger in opening up such cases under asepsis. If there are pronounced symptoms, one need not necessarily explore the brain; if symptoms are present and the patient apparently will not live long, one should not hesitate to explore. Dr. Cott has had good results in every case except the one of brain abscess.

TREATMENT OF ACTINOMYCOSIS AND BLASTOMYCOSIS WITH COPPER SALTS.*

ARTHUR DEAN BEVAN, M.D.
CHICAGO.

I desire to make a very brief preliminary report on the subject of the treatment of cases of actinomycosis and incidentally blastomycosis with copper salts. I do this at this time because I believe that, on account of the rather limited number of cases of actinomycosis and blastomycosis that come to one man, collective statistics of a trial of this method of treatment will do more to give us early definite and positive knowledge of its value than can be obtained by limiting it simply to the treatment of the few cases that come to my service.

Last year we had a half dozen cases of actinomycosis in my service, and since that time, at the Presbyterian Hospital, there have been a number of others, both in my service and in the service of Dr Billings and other attending men. We have found, as others have, in connection with the treatment of actinomycosis, that the iodid salts had very definite and very positive effects, and we have been successful in curing circumscribed lesions, especially about the mouth and the tongue and the neck, with iodid of potash combined with the x-ray, using the iodid, as has been emphasized by Dr. Ochsner, in an intermittent way, that is, giving the iodid of potash for a period, then discontinuing it, and then giving it again. We have noted this fact, that although marked impressions were made by the iodid salts on all cases of actinomycosis, that nevertheless the cases of abdominal actinomycosis and of lung actinomycosis were fatal in a large percentage of instances. Probably 70 per cent. of cases of abdominal actinomycosis are fatal, and probably 90 per cent. of lung actinomycosis are fatal in spite of the iodid treatment.

I want to refer to some of the cases which I reported last year. One patient with abdominal involvement, whom I reported as greatly improved under the iodid, has since died with a very definite brain lesion. I have no doubt, although we are unable to obtain a postmortem, that it was a ray fungus lesion of the brain. In one of our lung cases, on the other hand, there has been apparently a surprising recovery, and I want to make a statement in regard to that case. The patient whom I showed last year, at which time we found ray fungi in the sputum, was treated for a long time with iodid, using as high as 180 grains a day, with distinct improvement. Later a lesion of the testicle developed, which was opened, and found to be a chronic abscess, but no ray fungi were found by the operator, who opened this accumulation of pus, although it is fair to presume that it was a ray fungus lesion. The iodid was discontinued in May. The man was poor and very anxious to support his family by returning to his work. After returning to his work, which brought him out in fresh air most of the time, he improved steadily. A few days ago, when I saw him, we found no active evidence whatever of the process. In actinomycosis, as in tuberculosis and in many other lesions, a most important factor in overcoming the disease is undoubtedly the increased resisting power of the individual, and I think that factor should be considered in all of these cases. In spite of our iodid treatment, which has been so successful in local lesions, we have not been able to save most of our patients with lung involvement and our abdominal cases of actinomycosis. Because of that fact we have been looking out for some other method of treatment.

---

* Read before the Chicago Medical Society, 1905.

It is a well-known fact that the ray fungus occurs normally as a rust on grain. Within the last few years there has been a good deal of work done by scientific agriculturists with the use of copper in destroying parasites of vegetables. You are all familiar, I have no doubt, with a number of articles that have appeared in scientific journals and the lay press, showing the great destructive effect of copper in minute solutions in reservoirs of water, destroying the algæ and low forms of vegetable life. The ordinary rusts on grain can be readily destroyed by minute solutions of copper sulphate. The sulphate seems to be the most powerful of the copper salts. It is a very destructive agent to vegetable parasites and is well borne by animal organisms. My attention was called to these facts, and inasmuch as the ray fungus occurs in nature as a rust on grain, I thought it might be worth while to experiment with copper as a treatment of ray fungus in the human being. We have done this now in several cases. In one case we began with one-quarter of a grain of copper sulphate, three times a day, then increased it to half a grain, and we have given some of our patients as high as one grain, three times a day. The irrigation is made with a 1 per cent. solution of copper sulphate.

The French chemists (especially in connection with the subject of the possibility of chronic poisoning from the use of copper as a dye in canned vegetables, peas, etc.) have done much work to determine the toxicity of copper used internally for a considerable period, and have shown that copper sulphate can be used in doses of from two to eight grains a day, for six months at a time, without any deleterious effect to the individual. This was an important point to determine before making an extended trial of the salts. Copper occurs as a normal constituent in small amounts in the higher animal form, in some low animal forms as the oyster, it occurs in large amounts. Copper is readily absorbed by the stomach and intestines.

The so-called brass poisoning, which has been extensively discussed, is not due to the copper apparently, but to some other elements which enter into the brass. In addition to the use of copper in actinomycosis, I might state that we have used copper salts in two cases of blastomycosis. It is now a well-established fact (a suggestion which I made at the time of the report of the first case of blastomycosis in the West by Dr. Hyde, Dr. Hektoen and myself) that the iodid salts are curative in blastomycosis. The iodid of potash has a very powerful effect, used internally, on cases of blastomycosis. Many of these cases have been cured with iodid alone. For the superficial cases, the ordinary treatment of blastomycosis to-day is the combined use of the iodid and the *x*-ray. Possibly, as has been shown by some experiments conducted by Professor Haines and myself, the *x*-ray may produce a more powerful effect or rather the iodid may produce a more powerful effect in combination with the *x*-ray, because, as we have shown, free iodin is given off as a result of the action of the *x*-ray on iodid solutions. It has been found, however, that some of these cases resist the *x*-ray and the iodid treatment, and this is especially so with cases of general blastomycosis. I have been informed by Dr. Oliver Ormsby, who has seen so many of these cases of general blastomycosis, that they have all been fatal in spite of the iodid treatment. Therefore, we can not consider the iodid as a successful means of treating general blastomycosis, no matter how successful it has been in the cutaneous cases combined with the *x*-ray. Inasmuch as copper salts seem to have such an effect on actinomycosis, I thought we might use it in blastomycosis, and we have employed it in several cases.

ILLUSTRATIVE CASES.

The effect of the copper salts is shown in one patient with extensive blastomycosis. This man came from a western city, with extensive blastomycosis involving the entire dorsum of both hands, and we have been treating him with the copper salts. We have used the copper internally in one-quarter grain doses, three times a day, and later in half-grain doses, three times a day, and are using the copper sulphate as a wash in 1 per cent. solution. This right hand has almost entirely cleared up. It was a very serious, extensive lesion at first. The other hand is not as clean. There is still a lesion at one point which is suppurating, but there has been no extension, and very marked improvement under the copper treatment.

Another case is one of abdominal actinomycosis. Most of these cases are probably secondary to a ray fungus lesion, either of the appendix or of the cecum. The patient developed an enormous lesion which filled the entire pelvis. He was operated on, and an abscess cavity opened, fistulæ were found extending in all directions. The patient was placed on large doses of iodid of potash, and in spite of this treatment suppuration continued and fistulæ continued to develop. About six weeks ago I placed him on copper sulphate, using the sulphate of copper internally and as an irrigation. At the time the iodid was used we employed the *x*-ray, and there is a distinct coloring from the use of the *x*-ray on the skin of the abdomen. We had repeated demonstrations of the pathology. The ray fungus could be found in the pus at almost any time. There was extensive infiltration of the recti muscles by the process; fistulæ were developing at all times, and now this process has almost entirely cleared up under the copper treatment. The patient has gained twenty pounds in weight since the first of September (six weeks) under this treatment.

Now, I do not want to create an erroneous impression in regard to this treatment. We are simply experimenting with it, and I submit it to you with these results. I present the treatment as one that seems to have a logical basis and seems to have produced marked curative effects. As I have stated, I think a collective experimentation on our cases of actinomycosis and blastomycosis should be undertaken in order to determine the value of copper as a cure for these conditions.

It may be possible that as in syphilis, where certain cases are better handled with the mixed treatment of mercury and the iodin salts, so in actinomycosis and blastomycosis it may be shown by further trial that the mixed treatment of copper and iodin salts may be in certain cases the most effective.

REPORT OF TWO CASES OF TYPHOID FEVER, WITH PERFORATION AND OPERATION.[*]

JEROME B. THOMAS, M.D.
Attending Physician and Surgeon in Charge of Civil Government Sanitarium, at Baguio.
BENGUET, P. I.

A mild epidemic of typhoid fever occurred in this mountain settlement during the dry season just passed. There were seven cases in all, five of the patients being members of a gang of Japanese carpenters who lived on the lower floor of the servants' barracks of the Civil Government Sanitarium. The upper floor was occupied by Chinese and by native Filipino servants, but no case of typhoid occurred in the building, besides the five Japanese. The origin of the infection of the carpenters is uncertain, but it is probable that the first patient contracted the disease in one of the neighboring road-camps and that the flies, of which there was a plague during the dry months, carried the infection from his dejecta to the food of his companions. A general infection of the water or food supply of the neighborhood doubtless would have affected a larger proportion of the forty or fifty carpenters messing together, and many Filipinos would have been exposed.

One of the two patients concerned in this report was a Japanese carpenter; the other was a native Igorrote, a private in the local detachment of constabulary. The latter lived and messed in the constabulary quarters about one-quarter of a mile from the Japanese barracks, together with about thirty Igorrote and Ilocano comrades, and, as no other case developed there, it is fair to assume that he was infected at some other place, probably in the lowland road camps which he visited on duty from ten to fifteen days before he was admitted to the sanitarium.

Of the seven cases of typhoid fever, four were uncomplicated and rather mild in character; one was complicated by long-continued hyperpyrexia and parotitis; two were complicated by intestinal perforation and peritonitis, and the following is a brief résumé of their history:

Case 1.—Typhoid fever; perforation about fifteenth day of disease; operation; death.

Patient.—Guteng, Igorrote constabulary soldier, about 25 years old, was admitted to Civil Sanitarium, Baguio, Feb. 24, 1905.

History.—History of illness previous to date of admission unknown, except that he had been indisposed for several days, but had persisted in doing duty about the quarters. He had visited laborers' camps in the lowlands ten or twelve days before admission to the sanitarium.

Course of the Disease.—February 24, his temperature reached 105, pulse 104, and he had roseola on the back. The spleen was somewhat enlarged.

February 27, there was mild delirium during the day, and at night the patient left his bed and attempted to leave the ward. There was moderate diarrhea.

March 3, the case proceeded uneventfully, with tendency to delirium, until early this morning, when the patient gave evidence of severe pain in the bladder and penis immediately after passing urine. At 8 a. m., when I examined him, he was suffering from shock, was chilly, pulse thin and 120 and face pinched. The abdominal recti were very rigid. The abdomen was tender, but not markedly so.

The patient was stimulated with strychin and brandy hypodermically, heat locally, enemas of hot water and brandy and warm saline transfusions. There was no improvement or prospect of reaction by 4 p. m.

Operation.—At 4:30 p. m., ten and a half hours after the first symptoms, laparotomy was performed. Ether was the anesthetic used. An incision was made in the median line, one and a half inches long. Several ounces of flocculent serum escaped. There was no fecal odor. There was intense hemorrhagic peritonitis, the intestines having a mahogany red color. I examined about three feet of the ileum without finding the perforation. The pulse was too rapid and feeble to count, and death on the operating table seemed imminent. In view of the desperate condition of the patient, the character of the peritonitis and the possibility of the peritonitis being non-perforative, I decided to desist from the search for a perforation. I irrigated the peritoneum with hot saline solution and left the abdominal cavity full of it, and closed the abdominal wound with sutures, including all tissues. The pulse and general condition were better for half an hour after operation than all day, but soon declined again. The patient was left on the table and given high enemas of hot water and brandy. There was no reaction to hypodermics of adrenalin chlorid, one to twenty-five thousand, 30 minims and later 60 minims every fifteen minutes. The patient died at 9 p. m., about four hours after the operation.

Autopsy.—A partial autopsy was performed at 10 p. m. A perforation of the ileum was found in a coil of the intestine just above the bladder. The ulcer of the mucous membrane was about one-half inch in diameter, but the opening in the visceral peritoneum was small and apparently plugged with exudate. Several punched-out ulcers of the ileum were found reaching to the muscular coat. There was intense general hemorrhagic peritonitis, with large patches of plastic exudate.

Case 2.—Typhoid fever; apyrexia; relapse; perforation on thirty-fifth day of disease; operation; recovery.

Patient.—Musinka, a Japanese carpenter, about 25 years old, was admitted to Civil Sanitarium, Feb. 8, 1905, with a history of having been ill in the Japanese quarters with chills and fever for four days. There was no diarrhea.

Course of the Disease.—February 8, temperature 101.4, pulse 82, otherwise negative.

February 12, there was a diffuse rash on body, probably due to quinin; no splenic enlargement. Blood was sent to Manila for Widal test. Temperature gradually rose in afternoon to 103.2.

February 13, diazo reaction positive. Two roseolar macules were found on back.

February 14, several roseolar macules appeared on back and chest.

February 16, diazo test again positive; spleen normal.

February 19, Widal test of February 12 reported negative.

February 26, no fever for eight days. Patient sat up in chair for a short time. Evening temperature was 101.8.

March 10, temperature increasing daily, reaching from 104 to 104.5 in evening. The nervous system of the patient was much affected.

March 17, patient was groaning with pain about 4 a. m., when the nurse called me. The pain was referred to the region of the bladder, where patient kept his hand pressed. There was tenderness over the entire abdomen, but not marked. There was also board-like rigidity of the recti. Pulse was dicrotic. After consulting with Dr. Snyder, U. S. N., and Dr. Tormey, of Manila, who were guests at the sanitarium, immediate operation was decided on.

Operation.—March 11, 8:40 a. m., four hours and forty minutes after first symptoms manifested. Dr. Tormey gave ether. A median incision, one and a half inches in length, was made. A small amount of turbid fluid escaped; there was no fecal odor; there was a beginning peritonitis, and small areas (½ inch in diameter) of exudate on the ileum at regular intervals where the coils were in contact with the perforation. Over the bladder was found a perforation of the ileum; the opening into the peritoneal coat of intestine was one-quarter inch in diameter; the gut was red and much indurated for about one inch of its length, and the peritoneal coat was friable. I closed the perforation with interrupted silk sutures (Lembert), irrigated the intestine before returning it to the abdominal cavity, and then flushed the abdominal cavity. I left a small gauze drain reaching to vesicorectal fold, and closed the abdominal wound with silkworm gut, including all layers of tissue, and leaving lower angle of wound open for drainage.

Result.—March 12, the temperature dropped to 99.4 in fifteen hours. General condition was improved. I removed gauze drain at 9:30 a. m. and inserted a fresh one.

---

[*] Read before the Manila Medical Society, 1905.

March 13, patient was semicomatose, with fluttering of lids and contraction of flexors of hands and fingers. There was no tympanitis nor tenderness over the abdomen. There was no nausea. He began to take nourishment, clear chicken broth. The nervous condition improved during the afternoon.

March 14, patient passed a good night. He had some stupor and nervous symptoms in the morning, but they were less marked. A fresh crop of large roseolar macules, one-quarter inch in diameter, appeared on face, body and legs.

March 15, there was slight tympanites and a discharge of serous fluid from wound.

March 20, patient improving rapidly; small stitch abscess.

March 27, no fever since March 21; wound healed perfectly.

April 11, no fever for twenty days, but very constipated; patient began to sit up; no abdominal discomfort.

May 2, patient was discharged, cured, and was advised to wear a flannel binder, as a support, for several months.

The observation and treatment of these two cases, with but little aid from the few text-books at hand, have led me to the following opinions concerning the technic and the relative time of the operation for perforation; also concerning the pathology of perforation and the symptomatology of perforation proper in relation to that of the resulting peritonitis.

Since my first notes on the operations I have read two excellent reports on similar cases, one a report of 19 cases by Dr. Morris Manges,[1] and the other a report of 12 cases by Dr. George L. Hays.[2]

The conclusions of these authors confirm some of my half-formed conclusions and shed light on some of the obscure features of this most interesting and desperate complication of typhoid.

If these reports had reached me two months earlier than they did, I should have proceeded with the treatment of my two cases with much clearer ideas of both the pathology and surgery of the condition and with proportionately greater peace of mind. The general text-book, surgical or medical, is inadequate and unsatisfactory and, as Dr. Manges aptly remarks, "the lore which lies buried in society reports, hospital bulletins and medical journals is not the working stuff which reaches the general practitioner and guides him in the darkness and despair which envelope these gloomy hours" (of recognizing and treating perforation). How shall we determine the degree of shock that would make it advisable to postpone operative interference in these cases?

The "American Text-book of Surgery" advises as follows:

"He (the surgeon) should operate as quickly as possible, but not during marked shock if it is present. In this case he must wait, but only a reasonable time, for the rally, hurrying the reaction, etc."

In Case 1, while waiting for the patient to rally, I delayed longer than I should in the future. The patient never, in fact, rallied from the shock, but after the operation was finally performed his condition improved slightly for about an hour. In future, I should operate as soon as possible after establishing a diagnosis, except in case of extremest shock or of imminent death.

Rapid cleansing of the peritoneal cavity and the absorption of warm salt solution left in the abdomen should aid in relieving the shock. Rapid closure of the perforation, using local anesthesia or ether as a general anesthetic, should not add so much to the existing shock as would the unrelieved and progressive peritonitis and septic intoxication.

Case 1 emphasizes the difficulties offered by such complications as delirium, stupor or obtunded sensibility due to any cause, for such conditions may veil the symptoms of perforation and peritonitis until they have progressed too far to be susceptible of relief.

It will be noted that in Case 2 the operation was begun about five hours after the first symptoms of perforation were manifested. In both cases, about an inch of the intestine adjoining the large perforating ulcer was greatly inflamed and indurated and all the intestinal tissue was friable. Owing to the danger of the sutures cutting through and of the development of other perforations in the same area, I was impressed with the possible advisability of performing enterectomy under such conditions.

I am still inclined to believe that such an operation performed by a rapid and skillful operator would give the patient the best chance of recovery in a condition like that in Case 2, in which shock was moderate and the peritonitis incipient, by preventing the possibility of a secondary perforation from that area at least and perhaps diminishing typhoid intoxication by the removal of a large ulcerating nidus of the disease.

I note that Dr. Hays meets the danger of the rupture of sutures closing the perforation by anchoring that portion of the intestine to the upper angle of the abdominal wound.

Concerning the symptomatology, both cases presented typical and convincing symptoms of peritonitis from the first moment when complaint of pain gained the attention of the attendants.

The first patient was delirious and the time of the beginning of his pain was uncertain, but early in the morning of the day of operation he cried out frequently during efforts to urinate, and examination revealed undoubted signs of peritonitis. In both cases, the pain was referred to the region of the bladder, and to the penis in one case; there was marked rigidity of both abdominal recti muscles in both cases; there was tenderness over the entire abdomen, but especially the hypogastric region; in Case 1 the patient suffered from great shock, sweating and chill, with rapid intermittent pulse, pinched face, pallor; in Case 2 the patient had moderate shock; poisoning of the nerve centers in his case being usually evidenced by twitching of the muscles of arms and face and by a rapid fluttering of the eyelids, much like that observed in certain cases of hysteria.

I was impressed by the fact that there must have been an interval of many hours between actual perforation and the acute symptoms of peritonitis in Case 1 and a considerable interval in Case 2. In the latter case, there was a large opening into the intestine, giving evidence of a necrotic process of several hours' duration. In the former case, there was an advanced general peritonitis, and even in Case 2 there was a well-marked local peritonitis, with patches of exudate on the coils of the intestine in contact with the perforated ulcer.

It may be stated, therefore, that in both cases the symptoms calling attention to the perforation were due to secondary peritonitis and not to the actual rupture of the intestine.

In this connection, the following statement made by the "American Text-book of Surgery" appears to me to be misleading, namely: "When perforation occurs, the individual passes into a state of profound shock." This is true in a sense, but the passage into the state of shock is slow and proceeds *pari passu* with the septic peritonitis.

Dr. Morris Manges, in his report, makes the following pertinent statement: "It also becomes easy of comprehension that most physicians expect too many and too pronounced symptoms for an early diagnosis of perforation, for the appearance of which they often sacrifice the golden time for successful operative interference, since the fact is so often overlooked and so seldom understood that the perforation itself causes little shock and may even afford temporary relief."

---

[1] The Journal A. M. A., April 1, 1905, p. 1016.

[2] The Journal A. M. A., April 22, 1905, p. 1265.

Shattuck, Warren and Cobb[3] state that "early warning pains, earlier by a definite number of hours than the severe symptoms, occurred in 14 out of 21 cases of perforation reported by them."

All these facts emphasize the necessity of frequent careful palpation of the abdomen by the physician to determine at the earliest possible moment the occurrence of perforation before the resultant infection, peritonitis and shock have had a chance to proceed far in their development. Equally important is an alert and intelligent nurse, instructed to be on the lookout for the earliest symptoms of the complication.

Special Article

IMMUNITY.

CHAPTER XXXI.

ACTINOMYCOSIS.

Actinomycosis is a chronic infectious disease of man and animals, the lesions of which present, characteristically, a central mass of purulent and necrotic material containing colonies of "ray fungi," about or through which is disposed an abundant growth of granulation or fibrous tissue. In young or rapidly progressing lesions the amount of purulent material is large, while in older lesions well formed connective tissue is more conspicuous. The disease prevails especially among cattle, although it is met occasionally in the horse, hog, sheep, dog, cat and other animals; man is infected not infrequently.

Although the threads of fungi had been found in diseases resembling actinomycosis in 1845 and later, Bollinger, in 1877, gave the first accurate description of the disease in cattle, and in 1878 J. Israel described it as a new disease in man. A short time later Ponfick demonstrated the identity of bovine and human actinomycosis.

The Fungus.

The specific organism, *Actinomyces bovis et hominis*, on culture media consists of a mass of delicate threads which exhibit "true branching" and which, to a certain extent, segment to form "spores." The radially arranged groups of cells which occur as macroscopic granules in the pus of the actinomycotic abscesss, and which gave to the organism the name of the "ray fungus," are essentially a manifestation of parasitic existence; they are not formed in cultures. Each granule represents a colony of organisms the members of which possess club-shaped extremities, and in the center of the mass and extending from it are many of the delicate threads found in cultures of the organism. It grows on various culture media, often as a mold, and stains by Gram's method.

Resistance.

The actinomyces is an organism of considerable resistance. Cultures remain alive for one year or more when in a dried condition and the spores in one instance germinated after having been preserved for six years. A temperature of 80 C. for fifteen minutes kills the spores (Bérard and Nicolas). When suspended in bouillon spores are killed in fifteen hours by direct sunlight, but when thoroughly dried, approximately ten days' exposure produced no injury.

Attempts to place the actinomyces in a botanic system have resulted in many differences of opinion. By some investigators they are considered as an independent family midway between the hyphomycetes and the schizomycetes (bacteria), others place them under the hyphomycetes in the group of the streptothrix, while still others consider them as pleomorphous bacteria placing them in the group cladothrix. Petruschky recognizes actinomyces, streptothrix, cladothrix and leptothrix as genera in the family trichomyces, the latter belonging to the order hyphomyces. Biological variations which have been encountered have led to the recognition of several species of actinomyces, among which are a number of non-pathogenic forms. Wright limits the term actinomyces to those strains which produce colonies of clubshaped organisms in animal tissues.

Artificial Infection.

Many attempts have been made to transmit actinomycosis to animals by inoculating them with the diseased tissues of animals and man, and with pure cultures obtained from these tissues. Although a number of experimenters have reported positive results, by far the greatest number of the attempts have been fruitless. Probably Wright has been more successful than others in producing actinomycotic lesions in rabbits and guinea-pigs by the inoculation of pure cultures. Colonies of club-shaped organisms developed with considerable uniformity. In many instances the infection remains localized, not causing the progressive and destructive changes which actinomycosis produces when it occurs naturally.

Transmission and Infection Atria.

The organism has been found on grains, straws and other kinds of feed, and such bodies are commonly discovered in the initial lesion of the disease. Usually in cattle, and frequently in man, infection is accomplished by their implantation in the soft parts of the mouth (gums, tongue), or in carious teeth. Transmission of the disease to man by eating the meat of actinomycotic cattle has not been noted. In man the disease is primary in internal organs (lungs, intestines, liver, brain, etc.) in a large percentage of the cases, whereas "lumpy jaw" is rare. The disease extends locally by the gradual involvement of adjacent tissues, which in time become occupied by sinuses, abscesses and masses of connective tissue. Numerous "spores" and bacillus-like cells, having their source in the fungous threads, abound in the vicinity of a colony. The occurrence of such forms in leucocytes and other large mononuclear cells has led some to the view that the micro-organisms may be carried to neighbboring tissues or to distant parts as cell inclusions. In cattle the disease usually is more chronic than in man, more fibrous tissue is formed and metastases in internal organs are less frequent. In man the lesions are more purulent in character, large abscesses sometimes form as in the liver, and metastases in visceral organs are more common. Cases of general actinomycosis are occasionally met with in both cattle and man.

Prophylaxis.

Little can be said in the way of prophylaxis against actinomycosis. Knowing the part that infected grains, straws, etc., play in instituting infection, the practice of biting or chewing grains or of using straws as toothpicks, evidently is one which affords opportunity for infection. The presence of carious teeth has often been suggested as a predisposing condition for infection.

Immunity and Susceptibility.

Practically nothing is known concerning the degree to which susceptibility to actinomycosis prevails, and the question of immunity to the disease remains unexplored. The inability to reproduce the infection in animals at will renders impossible the systematic study of these questions. The presence of large numbers of polymorphonuclear leucocytes in the vicinity of the organisms suggests, but does not prove, that they may have some influence in combating the infection. Surely the abundant mass of connective tissue which develops about the abscesses and sinuses aids in confining the process to a definite region.

That the iodid of potassium has a curative influence on some cases of actinomycosis seems to have been well demonstrated. The principles by which it produces its effects are unknown.

MADURA FOOT.

Mycetoma, or Madura foot, resembles actinomycosis in the formation of absceses, sinuses and granulation tisue, but it shows a peculiar predilection for the foot, which probably is explained by the greater exposure of this part to infection.

---

[3] Report of Dr. Manges.

Mycetoma. This disease differs from actinomycosis in that the course is more chronic and it is never accompanied by generalized infection. The bones are not involved so frequently as in actinomycosis. Granules similar to those of actinomycosis are found in the cells, which, however, do not assume the pronounced club shape seen in colonies of the ray fungus.

Two varieties of the disease are known, one in which the granules are brown or black and another in which they are white or yellowish; the latter is encountered much more frequently than the former.

Pure cultures of the organism, which is called *Streptothrix maduræ* (Vincent), were first obtained by Vincent in 1894, and have been studied by a number of observers since that time. It bears a close resemblance to the actinomyces and by some is considered a variety of this organism. Differences between the black and white varieties are not clearly set forth. The disease occurs in southern Asiatic countries, in northern Africa, and in the United States (rare).

INFECTIONS BY STREPTOTHRIX, CLADOTHRIX AND LEPTOTHRIX.

Cultures of streptothrix, differing from the actinomyces, have been obtained from the lungs in a number of instances and in various countries. They have been found in such lesions as bronchopneumonia, or more extensive consolidation of the lungs, and in cases of empyema. In other instances organisms which have been classed as streptothrix or cladothrix have been cultivated from processes which resembled actinomycoces.

Streptothrix Infections.

Nocard considers a streptothrix as the cause of *farcin du bœuf* (farcy of cattle), a disease encountered especially in the countries of southern Europe, and similar organisms have been cultivated from suppurating or granulomatous foci in other animals.

Leptothrix buccalis, a thread-like organism which does not form branches and, hence, is not an actinomyces nor a streptothrix, is frequently found as a saprophytic organism in the mouth cavity, and a similar fungus, *Leptothrix vaginalis*, has been encountered in the vagina. Although organisms of this type are relatively harmless, they have occasionally been found in diseased conditions of the tonsils and pharynx.

Clinical Notes

A PRELIMINARY REPORT ON THE SPIROCHÆTA PALLIDA.

WESLEY E. TAYLOR, M.D.
AND
EDGAR G. BALLENGER, M.D.
ATLANTA, GA.

Having demonstrated the *Spirochæta pallida* in eight specimens taken from two chancres and a mucous patch, we desire to make a preliminary report of our findings, which were shown at the Atlanta Society of Medicine on Oct. 5, 1905.

The *Spirochæta pallida* was described by Schaudinn and Hoffmann last spring, and it is claimed that it is found constantly in the primary and secondary lesions of syphilis and may be an etiologic factor of importance. Whether or not it is the cause of syphilis remains to be seen, for it has not yet been isolated and cultivated and, of course, there must be a long series of cases by a number of observers before any conclusions can be drawn. The fact that these micro-organisms have been found by reliable independent workers in primary and secondary lesions and by Metchnikoff and Roux in monkeys inoculated with syphilis, and have not been found in any other lesions, seems to justify us in the belief that they may be the cause of this disease.

The stain that gave the best result was Giemsa's eosin and azur i and azur ii. With this stain the organisms appeared a translucent pinkish-red of high refractive character. They were best shown in slides where the red cells were of a light slate-green and the white cells well outlined in deep purple.

In length these organisms vary from one to six times the diameter of a red blood corpuscle and have many small curves, giving them a corkscrew shape, which is well marked in nearly every specimen. In thickness they appear a little narrower than a tubercle bacillus. In many cases there are very few spirochætæ, and, being very pale, they are difficult to find, while in other cases they are plentiful. One specimen showed nine in one field.

This organism may be differentiated from the *Spirochæta refringens*, which is larger, thicker, stains a deep blue and has much wider and less numerous curves. After once seeing the *Spirochæta pallida* it can not be easily mistaken for either the *Spirochæta refringens* or tissue shreds. In the beginning, however, the elimination of certain tissue shreds caused us considerable difficulty.

CLINICAL REPORTS OF SOME OF THE RARER FORMS OF HYSTERIA.*

C. C. HERSMAN, M.D.
Physician to St. Francis Hospital for the Insane, Alienist St. Joseph's Hospital.
PITTSBURG, PA.

Case 1.—Hilda M., aged 4, was admitted to the St. Joseph's Hospital of Pittsburg October, 1904.

History.—Mother died of tuberculosis; father healhty. She has always been delicate. She had typhoid fever at the age of 2½ years. Has a very bad temper, which is partially inherited. She has lived at various places, and has never been controlled. At times she is a lovely child, but when in a fit of temper nothing will induce her to smile. She is very thin, pale and delicate looking. She is poorly developed, with some marks of degeneracy.

The accompanying chart will show the hyperpyrexia suffered during one of the nervous attacks to which she is subject.

Case 2.—Katie H., aged 24, who had always lived at home; domestic; came to me in October, 1904.

History.—She has had stomach trouble and neuralgic headaches for two years. Three years ago she had a severe fright, followed in twenty-four hours by a heavy weight in the back, which traveled up the spine rapidly. The right arm became very heavy and its use was lost. There was a continual rotary movement to and fro (pronation and supination), with abduction and adduction of the elbow at the rate of 120 per minute, which lasted about a week. It stopped for two or three months, when it returned from another scare, which lasted a day or two. She was free for about a year. Since then she has had frequent attacks. They last from a few hours to two or three days. She has attacks in the leg and face. At times she has attacks in the left arm, when the elbow is flexed, the hand raised with a striking motion, very rapid. There is no pain with these attacks. When there is quiet in the limbs there are likely to be attacks of pain in the head and pain and heaviness in the back. She sleeps well. The motion may or may not cease while sleeping.

Examination.—Knee jerks present. No ankle klonus. Pupils react. Right shoulder seemed to be atrophied over the collar bone, and the upper edge of the pectoralis muscle during an attack in which I saw her. This appearance, however, disappeared when the motor attack passed off. The inner border of the scapula was prominent above and below. This also disappeared when the attack passed off. No puncta found. When the motion ceases, the use of the hand is normal. She has to sit crooked, spine flexed to left, and lean on the left elbow, or there seems to be an irritation at the os cervix. There is no mental trouble.

An attack of decided severity which occurred in my office with motor involvement of the entire right side and the left arm, lasting one-half hour, promptly disappeared on the suggestion that it would be train time in twenty-five minutes. She arose, arranged her toilet within ten minutes and went to the train.

---

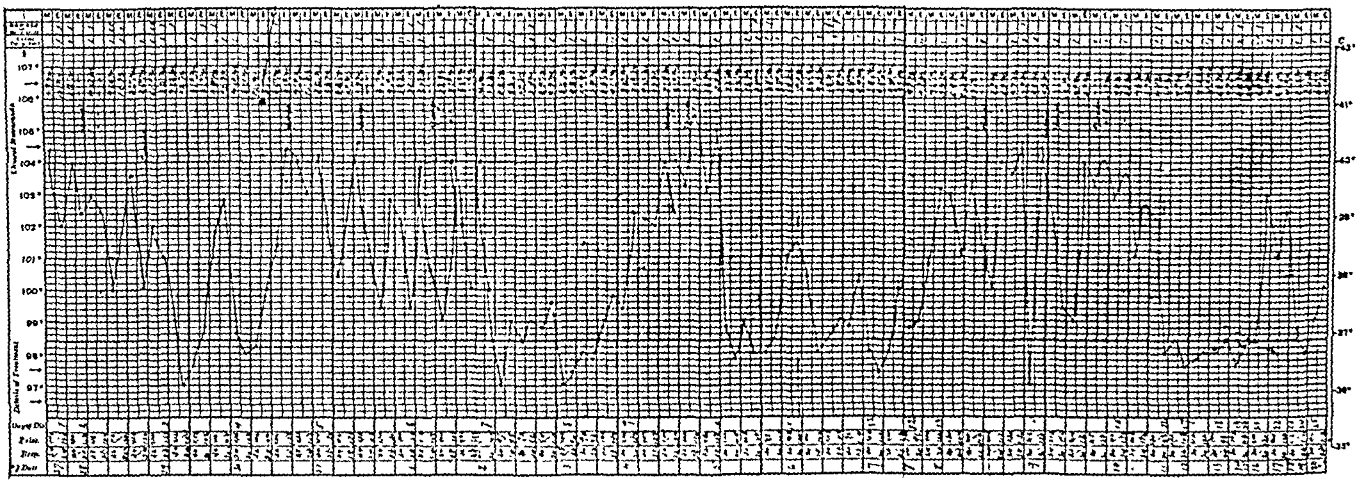
* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

The attacks cause her no fears, and she discusses them as being trivial. Both she and her mother think the attacks have made no inroads on her health, nor is there left any motor disability between attacks. The amount of force expended in an attack is very great, with no apparent fatigue.

Case 3.—H. K., aged 29, came to America from England at the age of 4 years.

History.—Parents living, one brother died of consumption at the age of 17 years. Otherwise the family history is negative. The sister next to him is very infantile; has a defect in her speech; rarely menstruates, and has some marks of degeneracy. His personal history showed no serious illness up to January, 1900, when he fell, striking the back of his head against a post, and being rendered senseless for half an hour. He was under a doctor's care for two weeks. Six months later he had a peculiar convulsive attack, in which there was a rhythmic spasmodic jerking of the diaphragm at the rate of 180 a minute. He has had eight of these attacks which last sometimes for eighteen or twenty hours. The attacks are always the same. In his attacks the amount of force expended is great without apparent exhaustion. Perspiration is excessive.

Examination.—The palate is highly arched, eyes small, abnormally shaped, balls prominent, pupils equal, reflexes normal.



Dr. W. H. Kirk has kindly furnished the report of the eyes which follows:

Vision: O. D. 20/40 —.
O. S. 20/40 —.
Correction: O. D. + 50 sph. = + 75 cyl. x 90° = 20/20 —.
O. S. + 50 sph. = + 75 cyl. x 90° = 20/20 —.

In the right eye the disc is slightly swollen and the vessels are very full, with hyperemic condition of the retina. The tension is normal, muscles in good condition, eye ball very prominent.

In the left eye the disc and vessels are swollen and very hyperemic. When examined over one year ago the choroid was in good condition, but on this examination, July 3, 1905, there is a slight choroiditis in the lower half of the eye, which does not seem to give him any trouble. The retina is in a fair condition, slightly congested, tension normal, eye very prominent, muscles in good condition.

Feb. 11, 1905, Pershing reported: The characteristic movement is a rhythmical oscillation affecting one part. In these two cases it was rapid, although it may be slow and apparently deliberate. If it had been organic other evidences of the reflexes would certainly have given some indications. The movements were somewhat grouped and the motions rhythmical, with no apparent fatigue, although the amount of force expended was very great. They were not controlled by restraint. Attention seems to aggravate the movements.

Krafft-Ebbing, in 1900, reported a case of hysteria simulating paralysis agitans.

Hysterical hyperpyrexia is usually found in the adult female from 18 to 40 years of age. It may, however, occur in the male and in very young children. I have seen the temperature go above 118 degrees in two adult females (reported at the Denver session, 1898), but in a child the highest was between 105 and 106. This was the one above reported. Such children are likely to have bad tempers, with little desire to control them.

Another form, hysteria agitans (motor hysteria, major hysteria), is seen mostly in the adult male or female. These attacks I have found to occur mostly in persons of a very unstable nervous system, often with degenerative stigmata. An attack may follow anything that weighs heavily on the mind. It may be confined to a group of muscles, a hemi-hysteria, or it may be a general attack. The motions may be to and fro, rotary or otherwise. The body, supine position, may perform all kinds of twitchings, abdominal motions, spasmodic jerkings of the diaphragm, similar to hiccough, rapid facial gyrations, rubbing the feet together, falling out of bed, etc. These motions may be very much modified if the attention of the patient can be engaged.

The movements are rhythmical, without apparent fatigue, though they may be violent and extend through hours of duration. It is possible by restraint to control the movements to a limited degree.

In Case 3 I have seen no signs of fatigue after 17 hours of continuous motion of intense degree.

The patient perspires excessively. The motions are usually controlled by hyoscin hydrobromate. I have not known the patient to have an attack when not working. He does much better when idle.

The following interesting questions arise:

Is there an irritating product formed within the cortical neurons?

Is there a paralyzing product within the cortical neurons?

Is there an irritating body or product in the plasma which bathes the nerve cell?

Is there an increase in the formation of cytotoxins?

Is there a decrease in the elimination of the metabolic waste product?

A CASE OF FOREIGN BODY IN A BRONCHUS.*

THOMAS A. CLAYTOR, M.D.
Professor of Therapeutics and of Clinical Medicine in the George Washington University, Physician to the Garfield and to the University Hospitals.
WASHINGTON, D. C.

Patient.—On March 19, 1905, I was called to a neighboring town to see T. G., a boy, aged 5 years and 7 months, who, for the past twelve days, had suffered with a bad cough and an irregular fever, ranging from 99 in the morning to 104 in the evening. He seemed cheerful and free from pain, but there was a frequent cough, consisting of two or three expiratory efforts. The temperature was 105; the pulse, 120, and the respirations, 60 a minute.

---

* Read before the Med. Soc. of the District of Columbia.

Examination.—The expansion was markedly diminished on the right side of the chest. The voice was too weak to allow of the detection of any differences in tactile fremitus, but there was certainly no increase over any area. Percussion showed a slightly higher pitch over the entire right lung, but only one small area of dullness extending from the angle of the scapula down to the liver. This area was oval and about 6 cm. wide at the broadest part. Over it the breath sounds were very faint and there was no increase in fremitus (an atelectatic area?). The respiratory murmur over the entire right chest was very faint and in marked contrast to the puerile breathing on the left. A sonorous râle could be heard in various localities over the right chest, but there were no fine râles anywhere. The leucocyte count was 42,000.

History.—The condition was at first quite puzzling, but it seemed clear when the following history was obtained:

On March 7, twelve days previously, the child, while eating peanuts, laughed and at once had a violent choking spell. The paroxysm continued until, while jumping up and down to shake off his overcoat, he said he felt something slip down and was at once relieved. He seemed much exhausted and slept for an hour. A physician was called, but found nothing abnormal. Immediately after his departure, however, a loud, wheezing noise developed in the chest which was noticed by the child himself and by those about him. That night the boy slept well and the next day he was as bright as usual, but toward evening he seemed sick and his temperature was found to be 101. From that time he had fever of a hectic type.

The second paroxysmal coughing attack occurred one week after the accident, it lasted about twenty minutes, was very violent and was accompanied by the free expectoration of mucus. The next day there was another paroxysm not lasting quite so long.

Course of the Disease.—The history, physical signs and symptoms all pointed to a foreign body in the right main bronchus.

On March 21, the child was brought to Washington. He stood the trip fairly well, but was much exhausted and seemed very sick all day.

Dr. Charles W. Richardson saw him with me and confirmed my findings as to the physical signs and also concurred in the opinion that there was a foreign body in one of the bronchial tubes of the right lung.

The question of an immediate tracheotomy was seriously considered, but abandoned in favor of bronchoscopy, and an instrument was telegraphed for.

March 24: The small area of dullness was unchanged, a loud, cooing râle could be heard on expiration all over the right chest. The respiratory murmur was much weaker on the right, especially anteriorly, and in the axillary region. Behind, the breath sounds were more nearly alike on the two sides. There was no tubular breathing anywhere.

March 25: The boy had the fourth coughing paroxysm since the accident. It lasted several minutes and was accompanied by hemoptysis. He was thoroughly exhausted afterward and at once went to sleep. Numerous large râles appeared which could be heard all the evening.

March 26: At noon the child had a violent coughing paroxysm lasting twenty minutes. Blood was expectorated and he complained of pain over the upper chest. Exhaustion was marked. When seen three hours later, the breathing was rather stridulous and air seemed to enter both lungs about equally. The object had evidently shifted its position. He was pale and his condition was such that I called Dr. Richardson, but before his arrival, at 4 o'clock, the physical signs had again changed to those so often before noted. The foreign body had dropped back to its original position.

March 27: Râles were heard at the bases of both lungs posteriorly. Air entered the upper right lobe freely, while the breath sounds were scarcely audible over the two lober lobes. Over the fifth rib in the parasternal line there was a tubular sound to the breathing.

The bronchoscope having at last arrived, Dr. Richardson tried, under chloroform, to introduce the smallest tube (7 mm.) through the larynx. This proved to be impossible and the child's condition at that time did not justify a tracheotomy.

March 28: We were greatly encouraged by the condition. Air seemed to enter the right lung freely, and the dull area had apparently decreased somewhat. The foreign body had evidently shifted its position, and we hoped it might have been dislodged and coughed up.

March 31: The temperature, which had been nearly normal for six days, began to rise. Numerous râles appeared over both lungs.

April 3: Temperature was hectic. There was still an area of impaired resonance below the right scapula. Cooing râles were heard on both sides posteriorly. There was a tendency to sweat at night.

April 4: The temperature was 103; pulse, 120; respiration, 32. Dr. J. D. Thomas found only a suspicion of tubular breathing over the lower right axillary line.

April 10: The temperature had been ranging between 98 and 104. The cough was troublesome. There were large, cooing râles all over both lungs, but less air seemed to be entering the lower right lobe.

As there was no longer anything by which we could definitely locate the foreign body, we did not feel justified in attempting further operative interference. There seemed nothing to do but to wait and to hope for spontaneous expulsion. Some observations which I concluded shortly after this time also made me hope for ultimate recovery. I found that the ordinary entire cooked peanut kernel, when totally submerged for twenty-six days, crumbled on pressure in much the same way that a piece of bread would when thoroughly wet. The same was true, though to a lesser degree, of pieces of the kernel which were kept wet, but at the same time exposed to the air, while an unbroken half-kernel, under the latter conditions, was still quite firm at the end of the period.

April 15: There had been an improvement. The temperature, though still hectic, was not so high, and the boy had been able to go out to drive. The motion of walking, however, made his cough more troublesome.

Examination on this date showed less expansion on the right side and less air entering the upper and middle lobes until after coughing, when the sounds became more normal.

April 18: The following note was made: "There is no difference in the amount of air entering the two lungs. If the foreign body is still present it does not, to any extent, obstruct any important bronchus. A cooing râle can be heard on either side on deep breathing. There is no dullness. The cough is less frequent and he seems quite like himself."

April 21: Because I did not think that the *x*-ray would show a nut, I did not consider it wise to give him the extra exposure of a trip to a laboratory until this time.

X-Ray Examination.—The examination was made by Dr. Charles F. Stokes. The fluoroscope showed a distinct shadow just to the right of the sternum, which in a radiograph was found to be opposite the fourth and fifth ribs anteriorly. This shadow, I am convinced, indicated a small area of infiltration set up by the presence of the foreign body. The boy gradually improved, the temperature became normal May 20 and has since remained so. the cough disappeared, and at a subsequent fluoroscopic examination by Dr. Stokes, one month later, no shadow was seen. The peanut had disintegrated and had been coughed up, most likely in small pieces, and the inflammatory products had been absorbed.

Remarks.—The fact that the *corpus delicti* never actually came to light naturally raises the question as to the accuracy of the diagnosis. It is well known, however, that children seldom expectorate. and this child in particular never did, except on the several occasions noted above, when mucus and blood were propelled from his mouth by the violence of the expulsive efforts rather than of his own volition. Therefore, the peanut may have been coughed up and swallowed.

The facts that his illness dated from the time that he choked while eating peanuts, and that the symptoms and physical signs were absolutely characteristic of a foreign body in a bronchus, I think, fully justify the diagnosis.

SATURDAY, NOVEMBER 11, 1905.

OYSTERS AND TYPHOID FEVER.

Industrial developments are continually giving rise to new and previously unsuspected opportunities for infection, and the task of the modern sanitarian is plainly one calling for eternal vigilance. The rigorous exclusion of sewage from some public water supplies and the filtration of others has diminished measurably the danger of typhoid-fever infection from drinking water, but while these reforms have been vigorously urged, another source of typhoid fever has been steadily increasing in importance. Over 25,000,000 bushels of oysters, valued at about $12,500,000, were marketed in the United States in 1902. The location of oyster beds in sewage-polluted estuaries is evidently a matter for real concern. It is sufficient to recall the mode of feeding of the oyster and the large amount of water that may pass through its gills to realize the extent of the danger. Professor Brooks, the distinguished Johns Hopkins zoologist, has said: "I think it is hardly an exaggeration to say that every drop of water that enters the Chesapeake Bay from the Susquehanna River has a good chance to be filtered through the gills of an oyster before it reaches the ocean."

In some localities it is a common custom among oyster dealers to place oysters shortly before marketing in the brackish water of creeks or bays for the purpose of "fattening." This somewhat delusive process of "fattening" consists in the osmotic absorption of water by the oyster removed from the salt water to the less dense brackish or fresh water, and results in an increased bulk and a lighter color. Should the water in which the oyster is put to be bloated and bleached chance to be polluted with sewage, it is easy to see how infection may result. Unfortunately, the localities chosen by the oyster men for fattening are likely to be selected on grounds of convenience rather than safety.

The nature and scope of the oyster problem on the sanitary side is well set forth in a recent paper by Fuller,[1] who discusses broadly both the evidence derived from a study of epidemics and local conditions, and also the bacterial and experimental data. In the case of one well-known British health resort cited by this author, there is evidence that over 37 per cent. of the total cases of typhoid fever occurring in a period of eight years were due to the consumption of oysters and other polluted shellfish.

In Great Britain, various official bodies have taken up the subject with the zeal usually shown in that country in the prosecution of sanitary reforms. In certain respects the satisfactory regulation and control of the shellfish industries presents numerous difficulties, and the problem is a complicated one. The fourth report of the Royal Commission on Sewage Disposal recommends the establishment of a new central authority equipped to investigate all phases and standing in direct relation to the proper executive bodies.

Among the recent experimental researches on the oyster question may be mentioned the work of Klein,[2] who points out that the longer persistence of *B. typhosus* in oysters out of water makes such oysters far more dangerous than if they were kept in water. It is further stated that infected oysters cleanse themselves quickly if put into sea water, and the suggestion is made that oysters be placed in a vessel of clear sea water and the water changed about once a day for several consecutive days. The practical limitations of such a mode of procedure hardly need exposition. The writer asserts that another shellfish, the cockle, is more dangerous than the oyster, as "it appears to offer to the *B. typhosus* even facilities for increase." This latter observation is so out of line with previous experience regarding the behavior of the typhoid bacillus outside of the human body as to need confirmation.

It is unfortunate that the situation in the United States in regard to the oyster industry is not one in which a central control can be well exercised. Consumers of raw oysters at present are quite at the mercy of oyster dealers, presumably of varying degrees of intelligence and conscientiousness. There should be some means of preventing the distribution of sewage-saturated oysters in any part of the country. Is this not something that the Public Health and Marine-Hospital Service should take up?

THE PATENT MEDICINE CONSPIRACY AGAINST THE FREEDOM OF THE PRESS.

A flood of brilliant illumination has been thrown on the methods by which proposed public health legislation has been defeated, but coincidently a heavy shadow is cast over the boasted freedom of the American press. "The fighting of public health legislation is the primary object and chief activity, the *raison d'être,* of the Proprietary Association." "The younger Pierce stated explicitly the agency responsible for the defeat of this public health legislation: 'We must not forget to place the honor where due for our uniform success in defeating class legislation directed against our legitimate pursuits. The American Newspaper Publishers' Association has rendered us valuable aid, . . . and we can hardly overestimate the power brought to bear at Washington by individual newspapers.' " "They printed scores of bitterly partisan editorials against the public health bill and against its authors personally, . . . and even in the persons of editors and owners went up to the state house and lobbied personally against the bill." "And of this one hundred millions which the people of the United States pay for patent medicines yearly, fully forty millions goes to the newspapers."

---

[1] Jour. of Franklin Institute, 1905.

[2] Report to Worshipful Company of Fishmongers, London. 1905. The Journal, March 25, 1905, p. 907.

Graphic and alarming as they are, the above extracts from the article, "The Patent Medicine Conspiracy Against the Freedom of the Press," in *Collier's Weekly* for November 4, give but an imperfect suggestion of the degradation laid bare therein. Even though he blush for the shackled press, whose owners and editors are shown to obey every order (and it is order, not request) of the Proprietary Association of America, every physician in the United States should read and preserve the article quoted from, and should place its evidence before the public. Aside from a few noteworthy exceptions, no agency of our time stands more in need of reform than does the press, and it is clear that pressure of public sentiment, aroused and fostered by physicians, is the only means by which this can be accomplished.

Fortunately, according to our thoroughly informed authority, "for the past the newspapers, in spite of these plain contracts of silence, must be acquitted of any very grave complicity. The very existence of the machine that uses and directs them has been a carefully guarded secret." In future, however, all will know why any paper opposes pure food and drug legislation. It must not be forgotten, either, that to a large number of newspapers this is a matter of life or death, for without the revenue from nostrum advertisements many of them must cease to exist. Full credit, too, is due to the newspapers of North Dakota, where alone there was flat disobedience to the orders of the Proprietary Association of America, and where, in consequence, a law was passed requiring nostrum labels to tell the true contents of the bottle or package. Since July 1 of this year nearly all nostrum advertisements have been withdrawn from the North Dakota papers, and the real struggle is proceeding.

The assertions and conclusions of the *Collier's* article are fully supported and confirmed by reproduced correspondence and proceedings and by photographed contracts and letters. The conclusions are indubitable. But let us beware of any pride of fancied superiority, at least until our own house is set in order. In the future, as in the past, evidence will be presented in these columns to demonstrate that the medical press is far from being free from similar control. Indeed, with few exceptions, the medical press is similarly subsidized by those proprietary manufacturers, who for the present confine their attention, actually or professedly, to the medical profession. Advertising contracts usually employed by the exploiters of certain proprietaries contain a clause requiring the editor, during the term of the contract, to publish free of additional charge one or more "original articles" concerning the products advertised. It is clear, then, that while we set out to initiate the reform of the lay press, it is essential that we rid ourselves of some of our own sins.

A NEGLECTED SOURCE OF TYPHOID BACILLI.

Many years ago Blackstein and Welch observed that after intravenous injection of typhoid bacilli in rabbits, bacilli may be recovered from the bile long after they have disappeared from the other organs. Since then we have learned that typhoid bacilli commonly find their way into the bile and the gall bladder in the course of typhoid fever, and that they may become the nuclei of biliary calculi and the cause of suppurative cholecystitis. In many instances, the bile has been found to be swarming with bacilli months and even years after the typhoidal attack.

While we have recognized the etiologic significance of their condition insofar as cholecystitis and cholelithiasis are concerned, it would seem that the hygienic significance of the gall bladder as a lurking place for bacilli has not been generally realized. It stands to reason that in a person so affected typhoid bacilli must pass into the intestinal contents and perchance be excreted in the stools. We have here, then, a hitherto somewhat unsuspected "bacillus carrier," which may become the source of sporadic as well as of epidemic typhoid.

The necessity of careful examination of the urine with regard to post-typhoidal bacilluria is more or less generally recognized, but hardly any stress has been laid on the possible hygienic dangers of the carriers of bacilli in their bile. We need careful observations as to the duration of the persistence of typhoid bacilli in the feces of typhoid convalescents, so as to learn more definitely the part played by bacillary bile invasion. When our knowledge in regard to this point is more complete than now, it may be possible to institute a more effective prophylaxis than the present, which is based almost wholly on general clinical experience rather than on comprehensive bacteriologic studies.

In the meantime, attention should be directed also to the problem of discovering some substance or method of destroying typhoid bacilli in the bile, just as the urine may be disinfected *in vivo* by means of hexamethylenamine (urotropin). At present surgical treatment of the gall bladder, which can not very well be extended to cases other than those showing indications of cholecystitis or cholelithiasis, offers the only chance for success.

It must be said that our present methods of prophylaxis against the spread of typhoid fever are somewhat lax so far as the typhoid patient as a source of dissemination of the cause of the disease is concerned. Cases of smallpox, measles, scarlet fever and diphtheria are, as a rule, isolated with great care until there is good reason to conclude that the patient no longer harbors the cause of the disease. Patients who have had typhoid fever, however, are permitted often to go abroad before it is known whether or not the bacilli have been completely eliminated from the urine and the feces. At all events, there is still much to be desired in this respect so far as typhoid is concerned.

Concerning the route by which bacilli reach the bile in typhoid fever, there seems to be little question but that it is by way of the blood stream. The bacilli occur in the blood even in mild diseases, and recently Doerr[1] in repeating the experiments of Blackstein and Welch, showed that in rabbits bacilli pass into the bile only after intravenous injection, and then by way of the cystic duct, i. e., through the liver. Organisms appeared in the bile in a few hours after injection, and Doerr noted their presence there for 120 days later. Injections of colon and paratyphoid bacilli gave results similar to those obtained with typhoid bacilli.

THERAPEUTIC DECADENCE IN BRITAIN.

The *descensus Averni* of therapeutics is not a purely American phenomenon. In Germany and Austria pathology has made such splendid strides and has attracted so much attention that it has monopolized interest to an extent that has entailed neglect of therapeutics. The same tendency has played a minor part in this country, and to that extent has emphasized the opportunity of the drug makers and nostrum makers to become our preceptors in therapeutics.

In England the profession suffers nearly as much as we do, and largely from the same source. International comity has progressed at least far enough for us fully to sympathize with the plaint which appears in the *British Medical Journal* for Oct. 21, 1905. Our contemporary, in its editorial caption, asks: "Shall we take our therapeutics from the druggist?" Its text is a circular from an American drug firm, which instructs physicians in the several physiologic actions of the common alimentary stimulants and laxatives, all the allegations of this purgative primer being offered as an introduction to the surpassing virtues of certain "lapactic pills." In the closing paragraphs our contemporary speaks as if describing conditions in America. "We know it is said that there are practitioners who are content to take their therapeutics from advertisements which reach them through the post, and that in spite of the numerous protests we receive against the plague of druggists' circulars, especially from across the Atlantic, our wastepaper baskets overflow with them, so that it seems possible that they fulfill their immediate object, which is the sale of the articles recommended. Probably the greatest hindrance to the healthy development of rational therapeutics, not only in the profession as a whole, but in each individual member, is the influence of advertising by which particular remedies are puffed into notoriety altogether out of proportion to their merits, and the quiet voice of criticism is drowned by the brazen trumpet of the nostrum vendor."

Herein lies the secret of our decadence. The distinctions between "proprietary" and "patent" drugs are not discernible to uninterested students of the situation. The physician, like the layman, uses many a remedy because someone "says it is good" for such and such conditions. This we do even when utterly ignorant concerning the composition of the medicament and concerning the physician who writes the testimonial. Of course, in such an atmosphere rational therapeutics finds no place. The manufacturer has done much to improve the appearance and the taste of the materia medica, and has contributed something to knowledge and to exactness of dose, but along with these good things has come the assumption on his part that he is the therapeutic instructor of the profession. Having assumed this position in many instances he has led us from good old remedies in attractive form to new agents of unguessable composition, which he tells us are good, and for which he persuades us to write testimonials.

Of course, we are to blame, and we must assume the responsibility. The manufacturer should not be too severely criticised so long as we enter no protest, swallow all that the advertising literature contains and prescribe any and every kind of nostrum without even enquiring whether it is the product of a reliable manufacturing pharmacist, or of some fake and anonymous chemical company. So long as we are contented, why should they worry who are making fortunes out of our credulity?

A NEWSPAPER FREE FROM NOSTRUM ADS.

"Thou hast a few names, even in Sardis,
That have not defiled their garments."

In *Collier's Weekly*, October 28, besides the illuminating article by Samuel Hopkins Adams, entitled "Peruna and the Bracers," excerpts from which we have already quoted,[1] a collection of letters is published, received by the management from various sources, and inspired by the first of Mr. Adams' articles. Lack of space forbids the reproduction of all these letters, interesting as they are, but one in particular deserves attention:

ONE RESULT OF COLLIER'S CAMPAIGN.

"The Marine Telegram.
"Marine, Illinois, Oct. 9, 1905.

"Editor *Collier's Weekly:*

"*Dear Sir*—The inclosed circular speaks for itself. Have been reading your articles against the patent medicine fraud. and heartily indorse the sentiment expressed. The *Telegram* has a circulation of only 500 copies per week, but the patent medicine fake can not buy space in the paper. Two years ago I canceled the last contract and am not renewing any. I am standing alone—all my exchanges are full of the 'gullible stuff,' but when such papers as yours approve and enter the fight there'll be 'something doing.' Did not intend to take up your time, but on second thought concluded to send you the circular to show you that your work is being felt. They are turning their attention even to such little fellows as we are. Keep after them, brother—they are hard hit and can't run very fast. Respectfully, L. C. Heim, *Editor Telegram.*"

---

[1] Centralbl. f. Bakt., 1905, 39, p. 624.

[1] See Pharmacology, November 4, p. 1422.

The circular to which reference is made is as follows:

"The Press Committee of the Proprietary Association,
184 La Salle Street, Room 1205, Chicago, Illinois.

"*To the Publisher:*

"We are inclosing copy of a communication which recently appeared in The Journal of the American Medical Association. It outlines the attack that is to be made on Proprietary Medicines.

"Believing you are interested in this matter, we also inclose for your information printed memoranda on the subject, which we hope you will read and preserve for reference.

"We should be pleased to hear from you at any time, and should you desire we can furnish you with interesting copy which briefly states the facts about patent medicines.

"The success of this agitation means the destruction of the Proprietary Medicine business, which is the system of medication now used with benefit by the great majority of the people.

Yours very truly,
The Press Committee,
"A. H. Beardsley, Chairman."

It is gratifying to know that an editor of a newspaper places honesty above advertising receipts and conscience above circulation. The Marine (Ill.) *Telegram* has a circulation of only five hundred copies per week, and is not afraid to say so, yet it may well be an example in business decency to the newsapers of the country, most of whose managing editors advocate strenuously, even vociferously, personal and civic decency on their editorial pages, yet admit, and even solicit, advertisements of palm readers, fortune tellers, abortionists, abortifacients, nostrum vendors and humbugs. But these journals are doubtless in the same position as one of our contemporaries, who said that "the editorial and advertising pages are entirely distinct."

INSURANCE AGAINST SEPSIS.

Physicians, as a rule, carry policies of accident insurance which include a clause indemnifying them for loss of time in case of septic infection arising in the course of professional duty. It is doubtful whether, when buying such a contract, physicians are as careful as they should be to determine just what hazard is covered by the "septic poisoning clause." An item in *The Spectator* (insurance), for Oct. 26, 1905, indicates that neglect of this precaution may lead to later disappointment. It seems that these clauses, so important to surgeons, physicians and dentists are variously worded, so that the amount of protection varies. Some of them provide that, to render the company liable, the production of the wound and the entrance of the poison must be simultaneous. This debars a claim for indemnity in case the infection occurred in a pre-existing abrasion, wound or hangnail. It is said that in one company's experience 90 per cent. of the claims under its septic poisoning clause have arisen from causes other than wounds suffered in operations. It is very evident that every physician who buys an accident policy with a septic poisoning clause should read the latter very carefully so as to be sure in advance just to what extent he is protected.

ALLEGED WHOLESALE POISONING.

One of the leading New York newspapers publishes the astonishing statement in its New Orleans correspondence that during the recent yellow-fever epidemic 3,000,000,000 of 1/100 gr. arsenic tablets were consumed in that city and vicinity as the result of the allegation of a Minnesota physician that arsenic is a preventive of yellow fever. The correspondent goes on to figure out the weight and bulk of these tablets; that they amounted to 26 tons and would fill a space of 7,000 cubic feet. The correspondent estimates that the people in and about New Orleans spent an aggregate of 2,083,409 days swallowing tablets, allowing one minute a dose. All this is soberly set down in the *New York World*, and was paid for at newspaper telegraph rates. Perhaps some additional figures may be of interest. Allowing 33 tablets to the grain, the above figures would make a total of nearly 190,000 ounces of straight arsenic, which would allow the better part of an ounce to every inhabitant of New Orleans, making it a pretty well "arsenicated" community, thus taking about 4,500 ounces *per diem*. The pathologic effects of arsenic should be pretty well demonstrated, and a yellow-fever epidemic ought to be well snowed under in such circumstances. Such, however, is newspaper medicine—sometimes.

INCONSISTENCY OF THE BRITISH MEDICAL JOURNAL.

Elsewhere we have quoted the views of the *British Medical Journal* in regard to "the plague of circulars," and the usurpation of therapeutic teaching by the makers of drugs. It is not a little astonishing, however, to find in the advertising pages of the same issue of that publication the advertisement of the firm and the identical article whose circular drew forth the eloquent comment of our contemporary. Further investigation of its advertising pages suggests that the British Medical Association's journal is not ready to join in the movement to suppress the present evil features of the proprietary trade. In its advertising pages appear advertisements of several products that we are sure would not bear critical investigation. While objecting to the flood of circulars from American pharmacists, our contemporary clearly has no evident objection to the influence of American cash in payment for the advertising of American proprietary remedies, some of which also are widely advertised in the lay press. The present movement, however, is somewhat new, and, as in our own case, existing contracts may have to be carried out, so that our contemporary yet has time to assume a more correct position, which we have no doubt it soon will do.

Education Is the Cure.—The best weapon of the right is education. The best way to overcome quackery and public indifference is through education. Hence we believe that every high school and college should offer courses in domestic hygiene. Under that term we mean an explanation of the nature of disease and its causation, the conditions of health in the home and about town, simple nursing, the laws of cure, etc. This is, of course, along the line attempted by the school physiology work of recent legislation, but it is yet so different that the need is not met by the teaching of the elements of anatomy and physiology to children. The course should discuss all the more common diseases and the principles of treatment. It should include vaccination and serum treatment. In fact, it should be a popular course on the subject of rational medicine. Only thus can the man who has a cure-all be forestalled.—*Journal of the Kansas Medical Society.*

Medical News

CALIFORNIA.

Mulcted for Mailing Obscene Literature.—Dr. Lawrence L. Sherrod, San Francisco, was fined $200 by United States District Judge De Haven October 25 for sending obscene pamphlets through the mails. He paid the fine and was discharged.

Personal.—Dr. Charles F. Millar has been confirmed chief surgeon of the Central Emergency Hospital, San Francisco.——Dr. Hayden M. Simmons, San Francisco, has been appointed a medical inspector of schools.——Dr. George W. Mallory, Santa Rosa, has taken a trip to New York.

COLORADO.

Personal.—Dr. and Mrs. Alfred B. Blackman, Colorado Springs, have returned from Europe.——Dr. Byron C. Leavitt, Denver, is visiting in Saco, Maine.

Pardoned.—The state board of pardons has recommended that pardon be granted Dr. Potts, Buffalo, who is serving a sentence of twenty years in the penitentiary for murder in the second degree.

Medical Board Resigns.—The entire medical board of Agnes Memorial Sanatorium, Denver, consisting of Drs. Arnold Stedman, William H. Bergtold, Carroll E. Edson, John A. Wilder and Lorenzo B. Lockard, has resigned. The members state as their reason that they do not approve of the present policy of the institution.

Warning Against Liquor Prescribing.—The city attorney of Colorado Springs issues a warning to physicians who give prescriptions for liquor. The ordinance provides that a prescription for liquor may be given by a physician only in the regular practice of his profession. It is not within the law for a physician to give, without examination and without a fee, a prescription to any person who simply wants liquor. The fine for violation of this section of the ordinance is from $100 to $300.

Vital Statistics.—During September 819 deaths were reported in the state, equivalent to an annual death rate of 17.6 per 1,000. Typhoid fever caused 41 deaths, diphtheria 4, and scarlet fever 3. During the month there were 334 cases of typhoid fever reported, 29 of scarlet fever, 23 of diphtheria and 14 of smallpox. As compared with the previous month, September shows a decrease of one case of diphtheria, 4 cases of scarlet fever and 17 cases of smallpox, and an increase of 86 cases of typhoid fever.

ILLINOIS.

Cornerstone Laid.—The cornerstone of the Taylorville Hospital was laid with appropriate ceremonies November 8. Bishop Ryan of Alton assisted in the ceremony. The building fund, so far, amounts to within $150 of the $10,000 required.

Personal.—Dr. Martin W. Cushing, Joliet, had another severe attack of heart disease October 30.——Dr. Frank P. Norbury, Jacksonville, has been elected vice-president of the Illinois Conference of Charities.——Dr. Alfonso C. Czibulka, Warren, has returned from an extended stay in Bridgeport, Conn.

District Society Election.—The Western Medical Society met at Alton October 27 in annual session, with an attendance of about forty. The following officers were re-elected: Dr. Henry W. Chapman, White Hall, president; Drs. Luther J. Harvey, Griggsville, and David W. Reid, Jacksonville, vice-presidents; Dr. Albyn L. Adams, Jacksonville, secretary and treasurer, and Drs. Thomas J. Pitner, Jacksonville; Levin H. A. Nickerson, Quincy, and Waldo Fisher, Alton, censors.

Aesculapian Election.—At the fifty-ninth annual session of the Æsculapian Medical Society of the Wabash Valley, held in Paris, October 26, the following officers were elected: Dr. Alsephus T. Robertson, Ashmore, president; Dr. C. E. Price, Robinson, vice-president; Dr. Harry McKennan, Paris, secretary and treasurer, and Drs. Henry E. Cushing, Champaign; Spencer M. Rice, Terre Haute, Ind.; Zachary T. Baum, Paris; Theodore N. Rafferty, Robinson, and Elmer B. Coolley, Danvile, censors. Robinson was selected as the next place of meeting.

More Asylum Changes.—Dr. Ira O. Paul, Winnebago, who was appointed interne at the Northern Illinois Hospital for the Insane, Elgin, has declined the appointment. Dr. Edward A. Foley has resigned as first assistant physician of this institution.——Dr. Edward F. Leonard, Chicago, has been appointed physician to the Illinois Central Hospital for the Insane, Jacksonville, vice Dr. Louis H. Clampit, Jacksonville. Dr. Harry C. Hardt, Hospital, has succeeded Dr. Elmer L. Crouch, Mount Vernon, as assistant physician of this institution.——At the Hospital for the Incurable Insane, Bartonville, Dr. Arthur K. Stangland, Chicago, has been appointed senior assistant physician, vice Dr. A. T. Burnham.

Diphtheria.—Dr. Guy L. Armstrong, secretary of the Taylorville Board of Health, writes that there has existed in Taylorville, Christian County, for several weeks a mild epidemic of diphtheria, probably 100 or more cases, about 25 of which are now under quarantine. Being mild and thus far with no fatalities, the epidemic is being given too little consideration generally, many doubting the diagnosis, although it has been demonstrated in all but one instance in which cultures have been made. Until the last few days it has been confined chiefly to one community and the children attending one school—which has been closed for some time. On account of the development recently of several cases in different parts of the city in children attending the various school, all the ward schools and the public library have been ordered closed.——The Humphrey school house, near Barrington, has been closed on account of diphtheria.——Richwoods township is suffering from an epidemic of diphtheria which may necessitate the closing of the public school.

Chicago.

Hospital Buys Land.—The Chicago Union Hospital has purchased the northwest corner of Wellington Avenue and Dayton Street, 90x264 feet, for $23,000.

Optimistic in Face of Difficulties.—Dr. Sarah Hackett Stevenson, who was stricken with cerebral hemorrhage two years ago, has sent greetings to her friends and expressions of gratitude that she still survives on the second anniversary of her affliction.

Coroner's Report.—During October the coroner investigated 285 deaths, of which 52 were found to be due to natural causes; suicide claimed 35 and homicide 17. Of the suicides 16 died by shooting, 3 by hanging and 7 by poisoning. Of the latter 4 employed carbolic acid.

Mortality for October.—During October 2,153 deaths occurred, 51 more than during the previous month, and 256 more than for the corresponding month of last year. The annual death rate was 12.73 per 1,000. Acute intestinal diseases caused 257 deaths; consumption, 242; pneumonia, 217; violence, including suicide, 205; heart diseases, 185; Bright's disease, 163, and cancer, 116.

Contagious Diseases.—During October three cases of smallpox were found in Chicago, and these all in one family.——There were reported 438 cases of diphtheria during October, and 50 deaths from this disease. During the week ended November 4, 120 cases were reported, with 16 deaths, and during the previous week 113 cases, with 16 deaths. The disease is distributed about equally in the various portions of the city.

Deaths of the Week.—For the week ended November 4 the deaths from all causes numbered 498, 28 more than for the preceding week, and 78 more than for the corresponding week of 1904. Pneumonia heads the death list with 77, followed by violence, including suicide, with 49, heart disease with 46, Bright's disease with 41, consumption with 40, intestinal disease with 32, nervous diseases with 21, and apoplexy with 20 deaths.

The Senn Dinner.—The following is the program of exercises for the Senn banquet: Presentation of medallion, Dr. Joseph D. Bryant, New York City; presentation of loving-cup on behalf of Dr. Senn's former students, Dr. Lewis G. Nolte, Milwaukee; response by Dr. Senn; "American Surgery," Dr. William J. Mayo, Rochester, Minn.; "The American Medical Association," Dr. Lewis S. McMurtry, Louisville; "The Medical Man as the Patient Sees Him," Hon. George R. Peck, Chicago; "The Medical Man versus the Surgeon," Dr. John A. Witherspoon, Nashville, Tenn.; "American Medical Literature," Dr. Charles A. L. Reed, Cincinnati; short reminiscences, anecdotes, etc., by Drs. Jacob Lang, Milwaukee; Edward Boeckmann, St. Paul; Fernand Henrotin, Daniel R. Brower, William E. Quine and others. Guests will assemble at the Fine Arts entrance to the Auditorium at 6:30 p. m., November 11.

INDIANA.

Fire Loss.—A fire in the library of the home of Dr. Benjamin F. Bye, Indianapolis, although of short duration, caused a loss of $2,500.

Fever Epidemic.—An epidemic of typhoid fever is raging at Mount Ayr; 35 cases have been reported, with 3 deaths.——It is reported that at Monticello there have been 10 deaths out of 15 cases.

Physician's Murderer Sentenced.—Alexander Kennedy, Lafayette, who shot and killed Dr. Philip J. Tresch, June 17, pleaded guilty to voluntary manslaughter October 26, and was given an indeterminate sentence in the state prison.

Clinical Society Formed.—The staff of the Deaconess Hospital, Evansville, has organized a medical society, to be known as the Deaconess Hospital Clinical Society. Dr. Charles Knapp was elected president and Dr. Charles B. Harpole, secretary.

District Society Meeting.—At the semi-annual meeting of the Thirteenth District Medical Society, held at Elkhart, October 19, 70 were present. Dr. William G. Wegner, South Bend, was elected president, and Dr. John C. Fleming, Elkhart, secretary and treasurer. The next meeting will be held in South Bend.

Cornerstone Laid.—The cornerstone of the main building of the Methodist Hospital, Indianapolis, was laid October 25. The chief address was made by the Hon. Charles W. Fairbanks, vice-president of the United States. United States Senator Albert J. Beveridge also delivered an address. The hospital is expected to cost $300,000.

Personal.—Dr. Frederick Herring, Goshen, observed his ninety-third birthday anniversary October 30.——Dr. Charles T. Bronaugh, New Ross, has returned from a trip to the Pacific Coast.——Dr. R. S. Byers, Trafalgar, was injured by a kick from a horse, October 29.——Dr. John M. Pulliam has resigned his position at the Logansport Asylum, Long Cliff, and will go into practice at Fort Wayne.——Dr. Austin Funk, New Albany, has gone to London.——Dr. James A. Comstock, Greenfield, went to Indianapolis October 24 to have an operation performed for disease of the bladder.——Dr. Clarence Kelsay, Evansville, has been appointed milk and food inspector by the board of health.——Dr. John B. Salb, Jasper, has been appointed division surgeon for the Southern Railway.

MARYLAND.

Left Large Estate.—The late Dr. George Johnson, Frederick, left an estate valued at $100,000.

Asylum Overcrowded.—The Maryland Asylum and Training School for the Feeble-minded is much crowded, there being now 200 inmates, with 170 applications for admission. The visitors will apply to the legislature for appropriation for additional buildings.

Delegates Appointed.—The governor has appointed the following as delegates to the southern conference on immigration and quarantine at Chattanooga, Tenn., November 9 and 10: Dr. John S. Fulton, secretary of the State Board of Health, and Dr. James Bosley, health commissioner of Baltimore.

Baltimore.

Births and Deaths.—The health report for October gives 822 deaths and 810 births.

Hospital Opened.—The new Franklin Square Hospital will be opened about December 1, with an address by the governor.

Plans for Hospital.—The architects have been selected to submit a general plan for the five buildings for the Hospital for Infectious Diseases. The site, in the eastern suburbs near the city almshouse, comprises about twenty acres. One building will be erected annually, the first being for diphtheria and scarlet fever.

Johns Hopkins Students.—At the Johns Hopkins Medical School there are 293 regular students. The smallest class is the first year, which numbers 58, including 7 women—the largest number of women there in any year. During the session a laboratory will be opened for instruction in operative surgery on animals.

Presentation to Hemmeter.—On November 15, the twentieth anniversary of his doctorate, an oil portrait of himself will be presented to Dr. John C. Hemmeter by his friends. There are ninety-five subscribers. Supervising Surgeon-General Walter Wyman of the United States Public Health and Marine-Hospital Service will make the presentation, and an address will be made by Dr. Warner Holt, Washington.

MASSACHUSETTS.

Bequest.—The Women's Charity Club Hospital, Roxbury, has received a bequest of $500 under the will of Edith G. Willard, Boston.

Illegal Practitioner Fined.—Hannah Porn, Gardner, was fined $100 in the Superior Court, Worcester, October 27, for the illegal practice of medicine.

Another Gift for Lowell Hospital.—Frederick F. Ayer has made another donation of $25,000 to the Lowell General Hospital, to be expended in improvements in accordance with the plan proposed.

Surgical Pavilion Opened.—The Douglass Surgical Pavilion, the gift of the governor to the hospital in his home city, Brockton, was dedicated October 31 with appropriate exercises. At the same time the Wellcome H. Wales memorial ward was dedicated.

Somerville's Donation Day.—Somerville Hospital benefited by its donation day by cash contributions of nearly $2,500 and quantities of clothing, food, linen and medicines. Much of the money was obtained by forming groups of five, each individual paying $50, and the whole sum, $250, being the amount needed to maintain a bed for a year.

Woman's Hospital Report.—The Free Hospital for Women, Brookline, reports that 308 patients were operated on during the past year, an increase of 20 over 1904. Dr. John Phillips Reynolds has resigned from the staff after a service of twenty-nine years. Although there are 42 beds available, only 30 can be used with the present limited nursing force.

Personal.—Governor Douglass has appointed Dr. Clarence F. Curley of Provincetown, medical examiner for the Third Barnstable district.——Dr. L. W. Starbird has resigned as surgeon of the Soldiers' Home.——Dr. Frederick Bogan, Boston, has been appointed assistant surgeon, with the rank of second lieutenant, N. V. M., and has been assigned to duty with the Ninth Infantry.

Good Work of Floating Hospital.—The Boston Floating Hospital reports that during its ten weeks' season, from July 6 to September 13, 279 patients were treated in the permanent wards. Of these 92 were discharged well, 73 improved, 23 not improved, and 91 died. The average stay of the patients was 13.76 days, a total service of 3,840 days. In the open ward 620 patients were treated, 50 trips were made down the harbor with these and on the average 47 were taken on each trip. Of these patients 35 were pronounced well, 366 improved, 216 unimproved (failed to come often enough to be benefited), 2 refused treatment, and 1 died. In the wards 140 were 6 months old or less, 65 from 6 to 12 months, 52 from 1 to 2 years, 13 from 2 to 3 years, 6 from 3 to 5 years, and 3 from 5 to 6 years. Among the day patients, including 66 transferred to the wards, 210 were under 6 months old, 227 from 6 to 12 months, and 249 over 1 year. The severity of the ward cases is marked by the fact that 26 died within 48 hours of admission.

MICHIGAN.

Detention Hospital Burned.—The Sheridan House, Jackson, which has been used as a detention hospital, burned October 20.

Diphtheria.—Mason County is at present suffering from a severe epidemic of diphtheria. Five deaths occurred during the last week in October and eight schools in the county have been closed.

Self-styled Physician Imprisoned.—"Dr." Francis Murry, Detroit, who has been annoying women in apartment houses, was found guilty October 13 and sentenced to the house of correction for ninety days.

Work on Hospital Begun.—Construction work has been started on the Hubbard Memorial Hospital at Bad Axe, which F. W. Hubbard is building and will present on completion as a tribute to his father, the late Langdon Hubbard.

Sanitarium to be Hotel.—The Alma Sanitarium has been leased for a term of years by Edward C. Mix, Missoula, Mont., and will be conducted as a health resort, open all the year around. The name of the institution has been changed to the Alma Springs Hotel.

Medical Cases Dropped.—The cases against "Drs." George W. King and Edward H. French, Grand Rapids, who were charged by Dr. Beverly D. Harison, secretary of the State Board of Examiners in Medicine, with having failed to take out certificates, have been dropped. King has left the city and French has promised not to practice medicine for a time.

Personal.—Dr. Robert H. Nelson, Hudson, has gone to Ann Arbor for operation.——Drs. Michael P. Fenelon and William A. Cotton, Escanaba, and Dr. Richard S. Forsyth, have been appointed physicians for the Delta County Hospital, Escanaba, for three years.——Dr. William J. Robinson, who was appointed city physician of Lapeer October 24, resigned October 25.——Dr. Charles W. Edmunds, Ann Arbor, has returned from Europe.——Dr. Clark R. Wilcoxson has been appointed health officer of Ypsilanti, vice Dr. Frank K. Owen, deceased.——Dr. Charles W. Yarrington, Centennial, has been appointed to the

Calumet & Hecla medical staff, vice Dr. William K. West, Calumet, resigned.——Dr. Martha C. Strong, Jackson, has returned from Europe.

MINNESOTA.

Hospital Association Incorporation.—The Lutheran Hospital Association of Minneapolis filed articles of incorporation with the secretary of state October 21.

Hospital to be Enlarged.—The Norwegian Lutheran synod will enlarge Luther Hospital, St. Paul, which has outgrown its present quarters, by the erection of a new building to accommodate 300 patients and to cost more than $100,000.

Personal.—Dr. William C. Voigt, Stillwater, was stricken with paralysis October 27.——Dr. Charles A. Lester, Wabasha, has been appointed local surgeon for the Milwaukee System, vice Dr. William F. Milligan, deceased.

Hospital Damages Settled.—The insurance appraisers have settled the damages sustained by the fire at St. Raphael's Hospital, St. Cloud, October 10, for $19,388.55. The hospital will be rebuilt and will be finished before spring.

Jury Disagrees.—After twenty-four hours' deliberation the jury in the case of Dr. Theron H. Bly, Minneapolis, indicted on the charge of performing a fatal criminal operation on Hilda Rosen, was allowed to disagree October 25, and was dismissed.

Chiropractic Wins Suit.—In the damage suit of A. J. Lindquist against D. W. Reisland, a chiropractic of Duluth, a verdict was given for the defendant, the judge ruling that chiropractic is a separate school and that the testimony of regular physicians against it is not admissible as evidence.

Red River Association Meets.—The Red River Valley Association met October 25 at Crookston and elected the following officers: President, Dr. Malcom McKinnon, Fosston; vice-president, Dr. Jacob S. Kjelland, Crookston; secretary, Dr. Theodore Bratrud, Warren; censor, Dr. Hodgson, Crookston; and delegate to the Minnesota State Medical Society, Dr. George S. Wattam, Warren, and Dr. Halvor Holte, Crookston, alternate. The association recommended that Dr. Malcom McKinnon, Fosston, be reappointed a member of the State Board of Health and that Dr. Theodore Bratrud, Warren, be selected as a member of the State Board of Medical Examiners.

Dispensing Physicians Must Pay Liquor Tax.—The deputy collector of internal revenue for the Minneapolis district announces that under a ruling handed down by the Treasury Department, he will have to collect a liquor dealer's tax from every physician who compounds his own prescriptions, or who uses alcohol or alcoholic liquors in so doing. The ruling expressly states that the tax must be collected from all physicians who keep a supply for their patients of "malt tonic," whisky, port wine, blackberry brandy and similar compounds, or use the same in compounding their medicines. The fact that liquors are furnished for medicinal purposes only makes no difference as to the tax.

KANSAS.

An Appeal to Kansas Physicians.—A prominent physician of America writes us that he believes that "the profession of this country is being frightfully humbugged by the secret proprietary manufacturers, much more so than are the people by the 'patent' medicine men; and the journals of the state societies must fall in line, even though they lose part of their advertising income. One of the most important things for the profession to learn is that if it does not support the medical journals, the nostrum men stand ready to do so." Are you ready to have the advertisements of proprietary medicines cut out of this jounal to the extent, say of $500? Or, don't you care a "continental" about the whole business? One of our councilors told us the other day that our men were not yet ready to put their hands into their pockets to support a journal without patent medicine advertisements. Is this true? Are the men of Kansas so blasé, so "blunted by the long disregard of the prohibitory law," so dull of moral fiber, that the question does not appeal at all to them?—*Journal of the Kansas Medical Society.* ["What shall the answer be"? We presume that all proprietaries are not to be eliminated, but only those which do not come up to a certain standard.—Editor.]

NEW YORK.

Consider New York City Water Plans.—The state water supply commission considered a petition and plans for taking water from the Catskills to supply New York City on November 3. The localities affected by these plans will be given a hearing within the next three weeks.

Hospital Gift Fair.—The German Hospital gift fair, which has just closed, was one of the greatest successes of its kind in the history of Buffalo. It is expected that more than $50,000 will be realized for the hospital, and with this amount many needed improvements, including a wing for private rooms and a nurses' cottage, will be made.

New York City.

Ambulance Wrecked.—An ambulance from the J. Hood Wright Hospital was wrecked recently. Both the ambulance surgeon and the driver escaped serious injury.

Fewer Milk Dealers on Trial.—There were only four milk dealers found guilty of selling adulterated milk by the Court of Special Sessions last week. These were fined sums varying from $10 to $30.

Quarantine Lightened.—Dr. Doty has suspended the regulation requiring vessels from southern domestic ports to stop at quarantine station for examination, except in the case of vessels from New Orleans. These will be required to stop until that city is officially declared free from yellow fever.

Cornerstone of Hospital Laid.—The cornerstone of the new Manhattan Eye, Ear and Throat Hospital was laid November 2 by John T. Agnew, a brother of the founder of the original institution. The new building will have a frontage of 125 feet and will be nine stories high. It will be ready for occupancy in about a year.

Hospital Staff.—The Philanthropic Hospital, which was recently dedicated, will have as its staff Drs. Heinrich Stern, Dexter D. Ashley, William S. Bryant, Ernesto Blasucci, George A. Crump, Julius R. Fabricius, David Flynn, D. Fredman, Victor A. Lyon, George B. McAuliffe, J. Smith Peterson, Edward C. Podvin, Thomas F. Reilly and Simon Strauss.

Contagious Diseases.—There were reported to the sanitary bureau of this city for the week ended October 28, 342 cases of tuberculosis, with 157 deaths; 262 cases of diphtheria, with 17 deaths; 94 cases of typhoid fever, with 19 deaths; 113 cases of measles, with 2 deaths; 61 cases of scarlet fever, with 4 deaths; 2 cases of cerebrospinal meningitis, with 5 deaths, and 85 cases of varicella.

New Wing for Hospital.—The new wing of St. Vincent's Hospital was formally opened November 2 by Archbishop Farley. This wing is supplied with a full equipment to accommodate 100 patients. Among the donors of funds for rooms in the new wing are John D. Crimmins, Adrian Iselin, Dr. Frederic S. Dennis, Jeremiah Campion, Mrs. James Butler and Mrs. John W. Mackay.

Give Money for Sanatorium.—The following contributions are reported for building a sanatorium for Hebrew children at Rockaway Park: Jacob Schiff, $10,000; Mortimer L. Schiff, $2,500; Adolph Lewisohn, $2,500; Felix M. Warburg, $1,000; Otto H. Kahn, $1,000; Paul M. Warburg, $500; Emanuel Lehman, $500; Daniel Guggenheim, $500; William Schole, $500, and Isaac Stern, $500. The furniture for the new building will be provided by Mrs. J. B. Greenhut.

Brooklyn's Water Supply.—Dr. Lederle has been at work investigating the condition of the water supply of this borough and expresses the opinion that the underground supply is pure and wholesome. The coli bacteria count was low and no intestinal bacilli were found. He thinks the epidemic of typhoid fever was not due to the water. However, about 45 per cent. of the water supply comes from the surface supply and this portion of the supply is menaced by pollution.

Inspect Cabin Passengers Also.—Commissioner of Immigration Watchorn has issued orders to the inspectors of the United States Public Health and Marine-Hospital Service to make thorough examination of all first-class passengers on incoming vessels. This order was prompted by the case of a man who came in the first cabin while his wife and children came in the steerage. It was discovered that this man, though diseased, managed to pass the casual examination accorded the first cabin passengers.

OHIO.

New Hospital Opened.—The new hospital at Wauseon was opened November 1.

Health Board Abolished.—The city council of Marysville abolished the board of health October 26 in order to settle the controversy between the board and the dairymen.

Contagious Wards Opened.—The new contagious hospital connected with the Toledo Hospital was formally transferred to that institution October 25. The building has two wards and is thoroughly equipped.

Physician Exonerated.—The suit of Frank Stroup against Dr. William J. Ritchie, Warren, in which damages of $10,000 were claimed for alleged negligence while attending the wife of the plaintiff, was decided in favor of the defendant October 19.

Diphtheria.—The epidemic of diphtheria at Leetonia is now believed to be under control; there has been only one death from the disease and one new case reported in the last week. ——Owing to an epidemic of diphtheria in district No. 11, the Storm's Station public school has been closed.——Diphtheria has broken out among the foreign population of Marblehead and the public schools have been closed.

Personal.—Dr. D. Clark Hoffman, chief surgeon of the Soldiers' Home, Dayton, has resigned, to take effect November 1, and Dr. Frank W. Roush has been appointed his successor.——Dr. John W. Murphy, Cincinnati, is seriously ill with what is believed to be an abscess of the frontal sinus.——Dr. George F. Brubaker, Springfield, has returned from a trip to the Pacific Coast.——Dr. William S. Bushnell and family, Mansfield, have gone to California for the winter.——Dr. D. R. Bookwalter, Dayton, is critically ill from tuberculosis.——Dr. George T. Harding, who has been on the staff of the Columbus State Hospital for four years, has resigned, to take effect November 15, in order to assume charge of the new National Sanatorium soon to be opened in Tacoma Park, near Washington, D. C.——Dr. Stanley R. Hutchings, Springfield, has been elected physician of the Children's Home, vice Dr. Walter N. Prince, resigned.——Dr. Sample B. McKerrihan, Portsmouth, was severely injured in a runaway accident October 26. ——Dr. Walter N. Prince, Springfield, has located in Red Lodge, Mont.——Dr. John J. Murphy, Lima, suffered painful injuries in a collision between his buggy and a street car October 24.

Pure Water for Cincinnati.—It has been finally decided that a solution of lime and sulphate of iron be used in connection with the new filtering beds of the water works for purifying the water, and not alum. The method of purification will be as follows: From the Ohio River the water will be introduced into two large settling reservoirs and allowed to remain there for from one to three days, according to its condition. It is then drawn off from the top of the reservoirs and passed through a regulating house, where the coagulant is to be introduced in solution. Thence it flows into three coagulating basins and allowed from one to six hours to pass through the basins. Next it is passed through the filters. These latter are 28 in number, each 28 by 50 feet, each acre of which is capable of filtering from 100,000,000 to 140,000,000 gallons in twenty-four hours, as against 2,500,000 to 3,000,000 gallons in twenty-four hours by the slow sand filtration with no coagulant as is used in Germany and some portions of this country. The filtered water is collected by a piping system and delivered into a clear water basin with a capacity of 18,000,000 gallons, whence it flows into the gravity conduit or tunnel, four and one-half miles long by seven feet in diameter, which brings the water to the western pumping station, whence it is pumped into the city mains for distribution in all parts of the city. Later it may be decided to roof over the clear water basin and the Eden Park reservoir. The cost before the completion of the entire plant will be in the neighborhood of $15,000,000.

PENNSYLVANIA.

Philadelphia.

Malpractitioner Sentenced.—"Dr." J. H. King was sentenced by Judge Sulzberger to three years in the Eastern Penitentiary October 31 for criminal malpractice committed on a young woman of Lebanon, Pa.

Jefferson College Library.—The annual report of the Jefferson Medical College library shows an increase during the year of 321 volumes and 100 pamphlets. The library now contains 3,315 volumes. Fifty-three current periodicals are regularly received.

Personal.—Dr. and Mrs. George Fales Baker will spend the winter in Europe.——Dr. Purves Stewart of England delivered a lecture to the students of the medical department of the University of Pennsylvania November 3 on "A Series of Cases of Nervous Disease."

Beriberi at This Port.—Out of 56 Chinamen composing the crew of the British steamer *St. George*, from Java, 8 were found to be suffering with beriberi on examination. They were, therefore, placed in the quarantine hospital at Marcus Hook, and the members of the crew were placed in detention quarters. The vessel will be thoroughly fumigated.

College of Physicians Meeting.—On November 13 Dr. Frank Billings, Chicago, will read a paper on "The Medical versus the Surgical Treatment of Diseases of the Stomach," and Dr. George E. Brewer, New York City, one on "The Indications for Surgical Intervention in Diseases of the Stomach, in the Absence of Symptoms of Perforation or Hemorrhage."

Hospital Reports.—The report of the German Hospital for the past month shows that 321 patients were admitted. There were 20 deaths during the month. In the dispensaries 4,626 patients were treated, and 3,072 of these were treated in the surgical department.——The report of the Howard Hospital for the month shows that 55 patients were admitted to the house; 150 accident cases were treated.——The Methodist Hospital admitted 70 patients and treated 563 in the different dispensaries.——The Charity Hospital treated 790 patients.—— The Women's Hospital admitted 116 patients, treated 502 new patients and 1,745 old patients in the various dispensaries.

Health Report.—The report of the Bureau of Health for the week ended November 4 shows that the total number of deaths aggregated 394. This is a decrease of 16 from the number reported last week, and an increase of 8 over that of the corresponding week of last year. The principal causes of death were: Typhoid fever, 7; diphtheria, 10; tuberculosis, 48; cancer, 22; apoplexy, 17; heart disease, 40; acute respiratory disease, 38; enteritis (under 2 years), 17; enteritis (over 2 years), 6; Bright's disease, 34; puerperal sepsis, 4; suicide, 8. and accidents, 15. There were 178 cases of contagious disease reported, with 17 deaths, as compared with 200 cases and 22 deaths for the previous week.

Society Meetings.—The Philadelphia Medical Examiners' Association held its first meeting November 8. The association is composed of medical examiners, and all men doing this work are entitled to membership. The qualifications are the same as for the Philadelphia County Medical Society, but the meetings are open to all physicians.——The American Society of Tropical Medicine will meet in the College of Physicians November 17.——The special lecture arranged by a resolution of the Philadelphia County Medical Society will be delivered November 15 at the College of Physicians by Dr. A. C. Abbott, president of the Philadelphia Bureau of Health, on "The Essentials of Successful Public Health Administration."

Opposes Contract Work.—At a regular meeting of the Medicolegal Society, held October 30, the following amendment to the by-laws was passed unanimously:

> *Resolved,* That on and after the first day of January, 1906, no member of this society shall accept the position of club, society, lodge or organization physician, or agree, or continue to do, any medical or surgical work for any club, society, lodge or organization at a less rate than the regular or customary charges for like services rendered by other physicians for patients not members of such club, society, lodge or organization. Also that in no case shall any physician agree to attend the families of the members of such club, society, lodge or organization at half price or a less price than the regular rate. Nothing in this resolution or section of the By-Laws shall be construed as preventing any member from attending the worthy poor at a less rate or to give free service to those who are too poor to pay anything, or acting as city, county or town physician, health officer, or under any political appointments. Any violation of this law shall be considered unprofessional conduct and render the member guilty thereof liable to suspension or expulsion from this society, as the society may determine.

RHODE ISLAND.

New Twin City Hospital.—The board of directors of the Twin City Hospital, Pawtucket, has rented the Mark Dean estate and will remove the hospital effects to the building on that property.

Epidemic of Diphtheria.—There is an epidemic of diphtheria among children who have been in attendance at the Calhoun Avenue primary school, Providence, and among others in that immediate vicinity.

Lawn Fete Receipts.—The lawn fête at the residence of Mr. and Mrs. F. W. Vanderbilt, Newport, in August last, for the benefit of the Newport Society for the Prevention and Control of Tuberculosis, netted $16,476 for the society.

New Hospital for Pawtucket.—Frank A. Sayles, Pawtucket, has announced that he will build and equip a large modern hospital as a memorial to his sister and mother. Work will be started next spring, the hospital will be complete in a year and will then be presented to the city.

Appropriation for Hospital.—Thirty-five thousand dollars has been appropriated by the city council for the aid of the Rhode Island Hospital, Providence, on condition that the hospital furnish twenty beds for the use and treatment of sick or injured employes of the city. Ten thousand dollars was also appropriated for St. Joseph's Hospital.

State Examining Physicians Appointed.—At a meeting of the board of trustees for the State Sanatorium for the Care of Consumptives, held in Providence, October 23, the following were appointed state examining physicians: Drs. Elisha D. Clarke, Woonsocket; Christopher F. Barker, Newport; Roland R. Robinson, Wakefield; John Champlin, Westerly, and Harold Metcalf, Wickford. The formal transfer and opening of the institution occurred November 1. Only residents of the state will be admitted, a minimum rate of $5 per week will be charged, and only cases will be admitted in which there is reasonable prospect of arresting or curing the disease.

SOUTH DAKOTA.

At Work on New Hospital.—Work has commenced on the new hospital building for Mitchell, which is to be completed before July 1 next.

Personal.—Dr. John W. Freeman of the Homestake Hospital, Lead, is taking a vacation, his place being filled by Dr. Daniel K. Dickinson, the original founder of the hospital.

TENNESSEE.

Personal.—Dr. E. Talmage West has been made chief surgeon of the National Soldiers' Home, Johnson City, vice Dr. Frank P. Robinson, resigned.——Dr. Philander D. Sims has been appointed city physician of Chattanooga, vice Dr. J. Sinclair Dyke, to take office January 1.——Dr. and Mrs. E. R. Hochstetter, Chattanooga, have gone to California for a year.

Will Admit Women.—The Tennessee Medical College, Knoxville, will admit women on the same terms as men, beginning with the term opening November 1. An arrangement has been made whereby the college will receive all students desiring to study medicine from the Lincoln Memorial University, Cumberland Gap.——Dr. A. G. Kern has become professor of surgery, vice Dr. John H. Morton, who takes the chair of obstetrics.——Dr. Walter S. Nash has had added to his chair of anatomy that of clinical surgery.——The college is spending $40,000 on a new hospital building which will soon be ready for occupancy.

TEXAS.

Diphtheria.—Diphtheria is reported to be prevalent at Tebo, Merkel and San Angelo.

Personal.—Dr. Benjamin M. Worsham, superintendent of the State Lunatic Asylum, Austin, has returned from New York, where he underwent a successful operation for appendicitis. ——In a runaway accident October 29 Dr. Joel M. Gooch, Temple, had a rib broken.

Hospital News.—All Saints' Hospital, Fort Worth, was formally opened on All Saints' Day, November 1. The first floor only is ready for patients. The building will have cost when completed about $18,000.——Plans for the new Santa Fe Hospital at Temple have been prepared. The building is to be a brick structure and will cost $50,000.

VIRGINIA.

Personal.—Dr. J. R. Speigh, city physician of Norfolk, has been suspended for sixty days pending investigation of a case of alleged neglect of duty.——"Dr." Rives Tatum, Harrisonburg, is at present in jail for practicing medicine without a license.

Fighting Diphtheria.—A quarantine has been established in Brandon district, Prince George County, to stamp out the diphtheria which has existed in epidemic form for a considerable time.——The public school at Disputanta has been closed on account of the disease.

GENERAL.

More Food Experiments in Washington.—It is reported that Dr. Wliey's "poison squad" is being reorganized. This time, according to the newspapers, the volunteers will be required to subsist chiefly on cold-storage products.

Instruction in Military Hygiene at West Point.—It is reported that the cadets at West Point Military Academy are to be instructed in the hygienic care of troops, and in the use of medicines for ordinary ailments likely to occur in small commands.

Information Wanted as to the Practical Lives of the Blind.—Dr. George M. Gould, 1722 Walnut Street, Philadelphia, will be grateful for any trustworthy information as to the methods which have been devised by the blind in overcoming their disability or in gaining a livelihood. Accounts of such lives, anecdotes, references to literature, etc., will be appreciated.

Nurses Wanted for Panama.—The government is endeavoring to secure "competent" nurses for service in Panama. These nurses are to receive only $50 a month, with free quarters and rations, and free transportation from New York to the Isthmus. It is said that the government's difficulty in obtaining competent women may be explained by the small salary as compared with that in the United States.

Army Reorganization Approved.—The Association of Military Surgeons of the United States, at its recent meeting, adopted the following resolution:

> *Resolved*, That the Association of Military Surgeons of the United States hereby expresses its entire approval of and earnestly urges the enactment of the bill to increase the efficiency of the United States Army, which bill was submitted by the Secretary of War to Congress at the last session.

Tuberculosis Exhibition.—The American Tuberculosis Exhibition will be held from November 27 to December 9 in the American Museum of Natural History, New York City. The authorities of the museum have placed at the disposal of the committee a large hall, in which will be shown elaborate models of sanatoria, with numerous photographs and charts. The New York Department of Health will be represented by demonstration of its campaign against tuberculosis, and the tenement house department exhibit will contain accurate copies of tenement house rooms under the old and new conditions.

Panama Hospital Interne Wanted.—The United States Civil Service Commission announces an examination November 29-30, at the regular places of examination throughout the United States, for male hospital internes on the Isthmus of Panama. An insufficient number of eligibles resulted from the examination held January 18 for this position. Full information concerning transportation to the Isthmus, conditions of employment, etc., is contained in Form 1417, which may be obtained from the United States Civil Service Commission, Washington, D. C. Age limit, 20 to 30 years; salary, $100 per month, with quarters, but without board and washing. Only graduates of reputable medical schools having a three years' course will be admitted to this examination.

Honors to Professor Ostwald.—The policy adopted by the authorities in France, Germany and this country by which there is an interchange of the services of professors of high rank in the leading universities has been continued by the sending of Prof. Wilhelm Ostwald of Leipsic to this country. He is the recognized pioneer in physical chemistry, preceding van t'Hoff and Arrhenius in his researches, and is now giving a course of lectures at Harvard University on physical chemistry. A banquet in his honor is held November 11 at Brooklyn, given by the physical science department of the Brooklyn Institute. The leading chemists in the universities east of the Alleghanies have been invited, and addresses have been promised by the president of Johns Hopkins, Prof. H. W. Wiley and F. W. Clark, both of Washington, and other chemists from Harvard and elsewhere. A large number of German-Americans who are interested in the chemical industries will also be present.

Army Medical School.—Col. Charles L. Heizmann, president of the United States Army Medical School, Washington, D. C., has made a report of the operations of that school, in which he says that the training of medical officers of the National Guard has so far proved unsatisfactory. He says:

> At this session of the school was inaugurated the training of medical officers of the militia of the states in everything pertaining to military medicine as distinct from naval, municipal, state and civil medicine, etc., in order that, under the Dick law, they might become qualified in the emergency of war to perform all the duties of military surgeons of the national army. If my interpretation of the purpose is correct I regret to report that the result was not satisfactory. All these officers were studious and earnest, and all would have contributed to the sanitary and disciplinary education of the organizations to which they belong had they returned to them. The majority, however, developed an intention to use the school as a means of employment in the regular establishment, thus to deprive their states of their services. One succeeded in receiving a commission in the army and two secured contracts. This result is interesting in demonstrating the need of some regulation by which the purpose of the law would be fulfilled in greater part, and at the same time secure for the regular and volunteer forces the best material possible. This last point will be attained by requiring all militia medical officers who have served one year as such and who have been recommended by the governors of their respective states to pass an entrance examination similar to those exacted of line officers by the artillery school and the infantry and cavalry school.

Yellow Fever News.—On November 5 only seven cases of yellow fever were under treatment in New Orleans.——The surgeons who worked under Dr. J. H. White during the campaign against yellow fever, on October 25 gave him a farewell banquet.——During the epidemic several physicians who, by reason of supposed previous attacks of yellow fever considered themselves immune, suffered infection. Consequently there is now some discussion as to immunity.——Georgia raised its quarantine on October 26.——The adjoining towns of Leeville and Côte Blanche have a joint combined population of about 950. Of these, during the six weeks' epidemic 788 had yellow fever and 104 died of the disease.——Governor Blanchard and Mayor Behrman each gave a reception to Surgeon White and his assistants at New Orleans on October 25. ——The situation at Pensacola is greatly improved, though one citizen secured a court order forbidding the health officers to fumigate his residence, thus threatening the cessation of all sanitary work.——The unexpended balance of the citizens' fund at New Orleans amounts to a little over $40,000. Publication of the detailed expenditures has made the *American* and its silly charges of graft look pretty small.——The Vicksburg epidemic is about at an end.

Plague in Hawaii.—Passed Assistant Surgeon Hobdy reports that two fatal cases of plague occurred in Waipahu Oahu on October 10. Waipahu is about nine miles from Honolulu; is the headquarters of one of the large sugar plantations, and is populated largely by oriental laborers. These laborers live in camp, reproducing in miniature the customs and conditions of their native land, and it is in one of these camps that five or six cases of plague have occurred during the last eighteen months. The two fatal cases mentioned occurred here in a Korean family, mother and daughter, and the bodies were cremated at the United States quarantine station October 11. The place was thoroughly cleaned up and disinfected by the local board of health, and no other cases have occurred. A third patient went into the Japanese hospital at Honolulu suffering with a supposed simple bubo, which was removed. The operator decided that the case was suspicious, and the bacteriologist to the board of health was called and pronounced the case plague. The patient was removed to the hospital for contagious diseases, where he died October 13, and the body was cremated on the same day. All possible precautions have been taken in cleaning up this man's dwelling and the hospital also. The source of infection could not be traced in any of these cases. A later cablegram from Dr. Hobdy states that another death from plague occurred October 24, and that outgoing quarantine has been instituted.

Cholera in the Philippines.—Dr. Heiser, chief quarantine officer, reports that while the total number of cases of cholera for the week ending September 23 is slightly in excess of those reported for the preceding week, yet the situation is not considered serious, and there is every reason to believe that the disease will be stamped out very shortly in the city of Manila. One very disquieting feature is the continued presence of cholera on the watershed of the Maraquina Valley, above the intake of the city water supply. Every effort is being made to guard against pollution, three troops of cavalry being engaged on this work. Dr. Heiser states that considerable anxiety was felt during the early part of that week on account of a report from Nueva Caceres that one case of cholera had made its appearance at that place. During the cholera outbreak of 1902 the disease appeared at Nueva Caceres almost simultaneously with its appearance at Manila, and since travel between Manila and Nueva Caceres during the present outbreak was practically impossible, except that which underwent the regular quarantine of five days, it was not likely that the disease could have been carried from Manila. Should this case have been correctly diagnosed, it would appear to afford additional evidence that the disease is endemic in the Philippines. No additional cases have occurred, however, and this fact will appear to throw considerable doubt on the diagnosis. Cholera in the provinces is still confined to about the same limits. The cases at Taytay have markedly increased until they have now reached a total of 56 cases, with 48 deaths. The total number of cases in the city of Manila since the outbreak has been 195, with 168 deaths. The number of cases in the provinces has been 260, with 213 deaths.

CANADA.

Improved Sanitation for Winnipeg.—Dr. R. M. Simpson, chairman of the Manitoba board of health, advocates for Winnipeg abolition of all box closets, a visible water supply, and a health officer and board of health independent of all aldermanic influence. By this means, he says, can that city free itself of the annual visitations of typhoid fever.

Ontario Board of Health.—The regular quarterly meeting of the Ontario board of health took place during the last week of September, when the prevalence of smallpox and typhoid fever were discussed. The board has decided to advocate vaccination and revaccination before manhood or womanhood has arrived. For September the number of cases of typhoid fever was 278, with 45 deaths. There were 13 cases of smallpox and 1 death.

Personal.—Dr. George W. Ross, Toronto, son of the former premier of Ontario, has been elected pathologist and registrar of the Victoria Park Hospital, London, England.——Dr. Claude Freeman, formerly superintendent of the Hamilton (Ont.) City Hospital, sailed November 4 from San Francisco for Chung-King, China, where he has received a hospital appointment.——Dr. E. S. Turnbull, Branchton, Ont., has received an appointment to the staff of the Protestant Hospital for the Insane at Verdun, Quebec.——Drs. G. D. Johnson and I. Glen Campbell, Vancouver, B. C., have declined to decide for a judge whether two Japanese who are ordered deported for trachoma, are cured or not, although two other Vancouver physicians say they are and two say they are not.——Dr. J. M. Lenny, Winnipeg, has been appointed division surgeon of the new transcontinental railway, the Grand Trunk Pacific.——Dr. F. Montizambert, director general of public health at Ottawa, is making his annual tour of inspection and is at present at Victoria, B. C.——Dr. George D. Porter, Toronto, has gone to Europe for a year's hospital work.

FOREIGN.

Plague in Australia.—Two fatal cases of plague occurred at Townsville, Queensland, during September; both patients were men between 20 and 30 years of age. Two suspects are under observation.

Yellow Fever in Mexico.—During the week ending October 23 Dr. Wilson of the Public Health and Marine-Hospital Service reports that there were three fatal cases of yellow fever in Vera Cruz.

Typhoid Fever in England.—During October there was an epidemic of typhoid fever at Basingstoke, and, according to the *Lancet*, the sanitary authorities of the town are being publicly accused of neglect of duty. It is reported that there have been about 128 cases, with 6 deaths.

Plague and Cholera in India.—In Bengal, during the week ending September 16, there were 93 cases and 72 deaths from plague. In the whole of India, during the same period, there were 3,939 cases and 2,871 deaths. In Calcutta, during the week ending September 23, there were 38 deaths from cholera and 13 from plague.

Physicians in City Councils.—A large proportion of the members of the city council of Paris, France, have been making a visit to London recently, as the guests of the London city council. The French council is presided over by a physician, Dr. Brousse, who has long held the post of president of the municipal council. A few years ago the president of the London municipal council was also a physician, Dr. W. J. Collins, and it is rumored that a physician is to be the next lord mayor of London.

Dysentery in Japan.—It is reported that dysentery has been prevalent in various districts in Japan during the present year. *Public Health Reports* states that the total number of cases and deaths from this cause from Jan. 1 to Sept. 5, 1905, with the figures for the corresponding period of last year, are given as follows: 1905, 20,917 cases, 4,002 deaths; 1904, 11,498 cases, 2,165 deaths. Dysentery has been particularly prevalent in the neighborhood of Osaka. In Yokohama cases of dysentery have not been unusually numerous, while Kobe has suffered severely.

Yellow Fever on the Isthmus.—According to *Public Health Reports*, no cases of yellow fever have occurred on the Isthmus since October 4, the last reported case having occurred at Matachin on that date. Considering the thorough work of inspection being carried on, it is justifiable to infer that no cases exist at present in Panama, Colon or the Canal Zone. The last case to occur in Cristobal was reported on August 7, since which time over 200 non-immune employes have been transferred to that place from Panama; yet nothing of a suspicious nature has been observed among them. This is looked on as good evidence that no infection exists there. The most rigid inspection of all hotels, lodging houses and places of public resort has failed to reveal anything suspicious. The fumigation of such places at regular intervals continues.

Koch Returns to Europe.—Robert Koch has returned to Berlin after nearly a year spent in scientific research in the tropics. It is rumored that he has discovered a new intermediate host for the transmission of a cattle disease prevalent in

Africa, a special kind of tick, but no official communication from him has yet been published. One of our German exchanges comments on his return that Germany and the world owe him a debt of gratitude, as he not only discovered the germ of cholera, but taught effectual measures to stamp it out. The recent epidemic of cholera in Germany has entirely died out, it states, no new cases having been reported for some time. The amazingly small number of cases—only 281 in all, with 90 deaths—and the tranquillity of the populace, are evidences of the progress which civilization owes to Robert Koch.

Yellow Fever in Guatemala.—Acting Assistant Surgeon Peters reports from Livingston that a case of yellow fever occurred in a native who went to Livingston from Sarstoon, a small place on the coast. The origin of infection was easily traced, as the patient had been sleeping in a house in which, during July, there had been a number of cases of yellow fever. When informed of the nature of the disease the governor immediately gave orders to have the house fumigated, and unless there are other infected houses which have been overlooked it is not likely that the infection will spread. This is the first case of yellow fever in Livingston since July 30, 1905, therefore the infected mosquitoes have been in the house for about seventy days, as the former cases occurred about July 20, and Dr. Peters has not heard of anyone being sick in the house since then.

Medical Substitution.—A physician at Düsseldorf, Germany, Dr. Weisbrod, conducts an establishment for treatment of cutaneous and venereal diseases. He is assisted in his practice by an undergraduate named Rössler, who has been for years in his employ. Weisbrod has been in the habit of entrusting his patients to Rössler, giving him blank prescriptions which the latter filled out for the individual case. As this substitution was not known to the patients, they supposed they were being treated by Dr. Weisbrod instead of by the assistant. When some of the patients learned the facts they accused Dr. Weisbrod of deception and carried the case into the courts. The claim was sustained by the legal proceedings, which imposed two months' imprisonment on Weisbrod and one month's on Rössler. The judge emphasized the deception practiced and especially the point that in venereal diseases such a manner of conducting medical practice might easily do great harm.

Surgeon Sued for Neglect by Nurse.—Our German exchanges relate that after a certain surgeon had operated on a patient, he left her in charge of the nurse, with instructions to put hot-water bottles in the bed. The nurse was 21 years old. She used such hot bottles that they burned the patient. When the latter aroused from the anesthesia she found her legs so badly burned that they did not heal for eighteen months, and a nervous affection was left, persisting to date. Damages to the extent of $1,000 were asked from the surgeon and nurse, and the first court decided in favor of the plaintiff, censuring the surgeon for leaving the patient in charge of such a young nurse. Appeal to a higher court resulted in the acquittal of the surgeon, the judge deciding that, as he was only in the service of the hospital, he was not responsible for the nurse supplied by the superintendent of the hospital for the case. Appeal to another court reversed this decision, the court holding the surgeon responsible, but a final appeal resulted in his acquittal at last as not being responsible for the actions of the nurse, while the full penalty was imposed on the nurse.

Continental Anglo-American Medical Society.—The American and English physicians residing in various cities in Europe and northern Africa associated themselves together several years ago for mutual friendship and good-fellowship, and to let the fact become known that there are reliable English-speaking physicians at various points on the continent. Once a year the members gather at Paris for an annual banquet, and the occasion is always a most delightful one. This year the banquet was held on October 5, during the same week as the Tuberculosis Congress, and the attendance reached 60 out of a total membership of 110. A number of noted guests from America and England were present. Dr. Lawrence Flick of Philadelphia responded to the toast, "America," and Sir William Hingston to "Canada." At the business meeting before the banquet, measures were discussed as to the best way of making the society known to the traveling public. The list of members is supplied each year to the consuls on the continent and to the publishers of the guide books and health resort bureaus, and copies are to be sent to leading physicians in England and America. Dr. Leonard Robinson, Paris, is the secretary.

Pharmacology

WAR AGAINST FAKE MEDICINES.

The Case of "Nature's Health Restorer," as Exposed by the Government.

Very few are aware of the work that has been done by the Postoffice Department, in connection with the chemical laboratory of the Department of Agriculture at Washington, to prevent the people being deceived by patent medicine frauds. Naturally the newspapers do not go out of their way to publish these exposures, and consequently little is heard of what is being done in this regard. On two former occasions we have published reports of such investigations, and this week we give another, using the matter as presented by the *Oil, Paint and Drug Reporter.*

The Postoffice Department, in connection with the general movement designed to bar fraudulent schemes of all kinds from the mails, has just taken action of much importance which marks a distinct advance over all attempts heretofore made to prevent the sale of fake medicines, nostrums, etc., with the aid of extravagant claims made in advertising literature circulated through the mails. A fraud order has been issued against the proprietors of a medicine known as "Nature's Health Restorer" on the ground that the claims of efficacy made are extravagant and untrue and therefore fraudulent. It is conceded by the postal authorities that the remedy is composed of standard drugs with important therapeutic properties, and that it is probably a valuable curative agent in the case of certain of the ailments for which it is advertised, and the fraud order is thefore based on the claims made for the preparation as a cure-all, which claims, the Department declares on the authority of the Department of Agriculture, can not be substantiated. It will be seen at a glance that the action of the Postoffice Department in this case is far more important than that heretofore taken with regard to medicines of any kind, and also that there are hundreds of proprietary remedies now being widely advertised and sold in large quantities that are undoubtedly open to the same objections that are raised against this particular preparation.

Through the courtesy of the Assistant Attorney General for the Postoffice Department, the *Reporter's* correspondent is enabled to present a full abstract of the report in this case, which discloses the methods employed by the department in the investigation and the character of the evidence on which the claims as to this particular remedy have been declared to be false and fraudulent. This abstract is as follows:

"The Western Medical Institute, which is owned and conducted by W. S. Burkhardt, is engaged in the manufacture and sale of a certain medicine which it styles 'Nature's Health Restorer.' The price of the medicine is $1 for a nine months' treatment. The selling of this medicine is conducted principally, if not entirely, through the medium of the mails.

"The literatuure used to promote the sale of this medicine is marked Exhibit A, B, C and D. Exhibit A is the circular which accompanies the free sample to the individual. Exhibit B is the circular which accompanies the free sample to the prospective agent. On the reverse side of Exhibit A appears the following:

"'CURE FOR CERTAIN DISEASES.

"'Kidney Disease. Nature's Health Restorer. One treatment will do its duty and cure the most stubborn case.

"'Liver Disease. Nature's Health Restorer will cleanse all the little blood vessels and absorbents, and thoroughly restore health.

"'Rheumatism. Nature's Health Restorer will cleanse the system of the acid and restore activity.

"'Erysipelas. Nature's Health Restorer will cleanse the impurities and humors of the blood, making the skin bright, clear and of a rosy hue.

"'Scrofula. Nature's Health Restorer will cure this disease, positively restoring the skin to its normal condition.

"'Neuralgia. Nature's Health Restorer, if taken as directed, drives all the pain away in a short space of time.

"'Female Complaints. Nature's Health Restorer will cure just as sure as you take it according to directions.'

"On Exhibit D is found the following: "'It (Nature's Health Restorer) will positively cure rheumatism . . . . nervous troubles . . . . female complaints, catarrh, liver trouble, kidney disease, ... or any blood disorders whatever.'

"On Exhibit C is found the statement:

"'We guarantee Nature's Health Restorer to cure all the diseases named on the treatment.'

"A sample of this medicine was submitted to the Department of Agriculture for analysis and report as to whether the same would cure the conditions represented above to cure. I quote as follows from that report:

"'This medicine possesses both tonic and laxative properties and is useful in cases of constipation and a condition of the system known as "run down," and will naturally alleviate affections resulting from the above conditions, but it will not, as a rule, cure "kidney disease, liver disease, rheumatism, scrofula, erysipelas, neuralgia" and a host of affections grouped under "female complaints." It will not cure Bright's disease, indurated liver or tubercular infection of the lymphatic glands. The per cent. (12.39) of ash shows that it is not purely vegetable, as claimed in Exhibit No. 1 (Exhibit A). The advertising tends to deceive and mislead would-be patients.'

"Sterling Ruffin, W. P. Carr and D. K. Shute, regularly licensed and practicing physicians of the District of Columbia, state that in their opinion medicines composed of the ingredients of 'Nature's Health Restorer' can not cure rheumatism, erysipelas, scrofula, catarrh, nervous disease, liver disease and blood disorders, as represented by that company. They state further, that, while the medicine might afford the same relief as that given by any laxative, as a rule no cure can be effected.

"From these statements it appears that the representations and pretenses employed by the Western Medical Institute to further the sale of 'Nature's Health Restorer' are untrue, and that the medicine is incapable of acting as the company pretends it will. A full opportunity to combat these statements was given the company, which has filed with the office the statements of Dr. A. L. Guertin of Cincinnati; statement of Dr. J. B. Ragland of Cincinnati; statement of Charles G. Merrell, chemist, of Cincinnati; testimonial of Thomas H. Wright, newspaperman of Cincinnati, and statement of W. A. Leach of Dayton, Ohio, former manager of the Western Medical Institute. Dr. Guertin states that he has been practicing medicine twenty-two years; that he has been acquainted with the medicines of the Western Medical Institute for about ten years; that he knows from experience in the use of these medicines that they are reliable remedies; that he has recommended them in cases of rheumatism, erysipelas, scrofula, catarrh, nervous diseases, female complaints, kidney and liver diseases and blood disorders, and that he knows of his own personal knowledge many cures that have been effected by these remedies. Dr. Ragland states that he has been practicing medicine for thirty-seven years; that he has been familiar with the medicines of this company for a number of years, and has found them to give universal satisfaction to people who have used them, and that they will cure kidney and liver diseases, catarrh and stomach troubles and also such diseases as are brought on by constipation of the bowels. The statement of Mr. Merrell deals with the well-known and recognized properties of the medicines forming the ingredients of 'Nature's Health Restorer.' The testimonial of Mr. Wright is to the effect that it has cured him of kidney, liver and stomach trouble. The statement of Mr. Leach is to the effect that, during the period he was connected with the company, many unsolicited testimonials were received from people who stated they had been cured of rheumatism, kidney trouble, stomach trouble, etc., by the medicine.

"These statements, submitted by the company, were forwarded to the Department of Agriculture for report thereon. The report of the Department reads in part as follows:

"'Mr. Charles G. Merrell is a member of the William S. Merrell Chemical Company, which manufactures many forms of medicinal remedies. The points made by him are conceded by us and are well known to the medical profession. The ingredients employed by the Western Medical Institute in the manufacture of "Nature's Health Restorer" are all recognized by the United States Pharmacopeia, and are known to possess valuable medicinal virtues. The statement that the advertisements of the "Vegetable Compound," which is understood to be the same as "Nature's Health Restorer," are in no way extravagant is certainly not in accord with the experience of others.

"'Mr. Merrell also states that there is present in this medicine "a proportion of terra alba." This confirms our statement in a former letter to you to the effect that "Nature's Health Restorer" is not purely a vegetable compound. Terra alba certainly does not have its origin in vegetables.

"'I note what the two physicians say. This is diametrically opposite to the statements submitted to your department on a former date from the most reputable physicians of this city. I would suggest that the standing of these two physicians be investigated.

"'Mr. Wright's statement, in my opinion, does not deserve consideration. In the first place, he can not possibly be conversant with the nature of the various diseases he enumerates, and, in the second place, he claims to have been cured of kidney, liver and stomach troubles, and from this he jumps to the conclusion that it "can be justly recommended to cure . . . sick headache, fever and ague, catarrh and scrofula." This conclusion is without foundation.

"'The affidavit of Mr. W. A. Leach, for several years connected with the Western Medical Institute, embodies business principles, and should be considered in finally summing up this side of the case, but it contains nothing which tends to make any one versed in the art of medicine believe that "Nature's Health Restorer" will do anything more than any other ordinary laxative medicine.'

"In accordance with the suggestion of the Secretary of Agriculture that the statements and standing of the two physicians, A. L. Guertin and J. B. Ragland, be thoroughly investigated, the matter was submitted to the inspector at Cincinnati. Drs. Ragland and Guertin admitted to the inspector the falsity of their affidavits and retracted the statements therein made. These statements are, therefore, entitled to no credit in determining the issue whether this medicine will cure the diseases which the company represents that it will cure, and which the Department of Agriculture and Drs. Ruffin, Carr and Shute state it is incapable of curing. Even Drs. Ragland and Guertin, when interviewed by the inspector, admitted that these medicines are incapable of making the cures represented by the company. It seems that, while this medicine possesses merit as a laxative, with some tonic properties, the representations of the company that it will cure rheumatism, erysipelas, scrofula, catarrh, nervous diseases, neuralgia, female complaints, kidney disease, liver diseases and blood disorders are wholly without warrant, and that the well-known medical properties of the ingredients of 'Nature's Health Restorer' deny its efficacy to cure those conditions. The evidence is therefore clear that the representations quoted above to the effect that this medicine will positively and certainly cure the conditions mentioned are false and fraudulent, and without warrant.

"The following representations also made by this company in the promotion of the sale of this medicine are found to be false and fraudulent:

"'We have discovered one of the most valuable treatments that was ever placed within the reach of the public.'

"'We have labored for many years to discover this peerless remedy.'

"'The best, safest and most beneficial remedy known to the medical world.'

"'Its results are marvelous and something that has never been produced by other treatments which have been prepared by physicians known to be the best our country affords.'

"'Our past experience covering a number of years has taught us to regard with wonder and admiration our phenomenal success.'

"'These medicines . . . are priceless as the dazzling jewels in the crown of the proudest king on earth.'

"'Our great remedy.'

"These representations, in their entirety, are calculated to create, and do create, in the mind of the reader that the medicine of the Western Medical Institute is a new discovery in the field of medicine; that it possesses unusual and extraordinary efficacy and is far superior to any medicine 'known to the medical world.' As a matter of fact, this medicine is not new, its ingredients are all well known and have been for years and are constantly used by physicians. The above representations are therefore misleading and carry a false idea to the mind of the reader. The company attempts to explain that its claim to the discovery of this medicine lies in the proportions used. The mere fact, however, that this company uses the constituents of this medicine in slightly different proportions from any others is wholly insufficient to warrant the extravagant statements noted above, and does not remove from them their misleading and deceptive character.

"The evidence in this case satisfies me that the pretenses and representations used by this company to promote the sale of this medicine are false and fraudulent, and calculated to deceive, and that the medicine will not cure the diseases that the company represents it will cure. It follows that the scheme is one devised for obtaining money through the mails on pretenses, representations and promises which are false and fraudulent within the meaning of Sections 3929 and 4041 of the Revised Statutes. I therefore recommend that fraud order be issued against the Western Medical Institute at Cincinnati."

Wine of Cardui.

Prof. Henry Leffmann of Philadelphia writes us that on reading the remarks of Mr. Patten of the Proprietary Association, and of the Chattanooga Medicine Company, as published in The Journal two weeks ago, he decided that it would be worth while to examine a bottle of the "Wine of Cardui" put out by the companies with which Mr. Patten is connected. He says: "I bought a bottle to-day. I find that the article contains considerable alcohol. It is, therefore, of the type of 'booze' that Mr. Patten excludes from the list of true proprietaries. The label states 'this pure wine is a simple vegetable extract, without intoxicating qualities, and has proved to be the most astonishing tonic for women known to medical science.'

"It is a turbid liquid of a dirty brownish tint, with an odor partly alcoholic and aromatic, partly disagreeable. The taste is markedly alcoholic and also nauseous. The residue on evaporation is about 7 per cent. A tablespoonful heated to boiling in a test tube gives enough alcohol promptly to produce a flame five inches long. There is no question, therefore, that this is an intoxicant in the scientific and practical sense of that term."

Prescribing Nostrums in Indiana.

A reference to our Medicolegal Department this week will show that in Indiana they have a law providing that anyone who prescribes a drug or medicine, the true nature and composition of which he does not make known, but avows to be a secret remedy, thereby endangering the life of another person, is liable to a fine of not less than $30 nor more than $100, and to be imprisoned in the county jail for not less than sixty days nor more than six months. If this law means all that it appears to mean, and if it is enforced, it will have a tendency to check nostrum prescribing in Indiana.

Marriages

Otto G. Smersh, M.D., Dodge, Neb., to Miss Anna Longarre of Omaha, October 28.

Charles W. Bonynge, M.D., to Miss Juliet Phelps, both of Los Angeles, October 24.

Samuel P. Free, M.D., Perry, Iowa, to Miss Flora Allen of Earlham, Iowa, October 25.

J. B. Person, M.D., Selma, N. C., to Miss Hattie Moseley of Kinston, N. C., October 25.

Samuel R. Upham, M.D., to Miss Marguerite Bailey, both of Claremont, N. H., November 7.

Harry N. Anderson, M.D., to Miss Margaret Holmes, both of Scranton, Iowa, October 18.

William Harrison Ballard, M.D., Los Angeles, Cal., to Miss Louise Baker, October 27.

James W. Dalbey, M.D., to Mrs. Fannie Schneider, both of Cedar Rapids, Iowa, October 30.

Marvin Pence, M.D., to Miss Elizabeth Hoover, both of Nicholasville, Ky., November 2.

August Knoefel, M.D., Linton, Ind., to Miss Minnie Kierner of New Albany, Ind., October 25.

William H. Shaver, M.D., Madelia, Minn., to Mrs. Olive J. Reimstad, Minneapolis, October 25.

Thomas Charles Buxton, M.D., Decatur, Ill., to Miss Anna Strope of Oreana, Ill., November 4.

Fred E. Clow, M.D., Wolfboro, N. H., to Miss Jessie F. Beless of Waltham, Mass., October 25.

L. Napoleon Boston, M.D., Philadelphia, to Miss Caroline Crandall of Westerly, R. I., October 28.

Delmar Smithers, M.D., Chesapeake City, Md., to Miss Annie Young, at Belair, Md., November 1.

E. M. Holmes, M.D., Readyville, Tenn., to Miss Elizabeth Vaughan of Shelbyville, Tenn., October 18.

Fred B. Jewett, M.D., Howard, R. I., to Miss Caroline Maloon of East Machias, Maine, August 22.

Carl Clifford White, M.D., Mathews, Va., to Miss Emma Lee Smith of Charlottesville, Va., October 26.

Charles E. Patterson, M.D., Grand Rapids, Mich., to Miss Helen G. Moore, at Denver, Colo., October 24.

Louis D. Mead, M.D., Byron Hot Springs, Cal., to Miss Charlotte Lanneau of New York City, October 31.

Herbert McKay Coulter, M.D., Azusa, Cal., to Miss Edith Sylburn Isham of Pasadena, Cal., October 25.

Edward Franklin Lovejoy, M.D., to Miss Edith Marie Fisher, both of Chattanooga, Tenn., October 25.

John Franklin Crawford, M.D., Hampton, Ky., to Miss Annie Patton Bridges of Louisville, October 31.

Frank H. Edwards, M.D., to Mrs. Clara Caton Sirrine, both of Evanston, Ill., in Waukegan, Ill., October 28.

William Fayette Owsley, M.D., Burkesville, Ky., to Miss Anne Pearl Owings of Lexington, Ky., October 25.

Lieutenant George F. Adair, assistant surgeon, United States Army, to Miss Pearle Parke of Chicago, November 8.

J. R. Sutton, M.D., Elk Park, N. C., to Miss Margarite Turner of Rutherford, N. C., at Elizabethton, Tenn., October 25.

Timothy G. Harriman, M.D., Hampton, Iowa, to Miss Nancy Masters of Long Beach, Cal., at Council Bluffs, Iowa, October 27.

Eugene H. Mullan, M.D., assistant surgeon, United States Public Health and Marine-Hospital Service, to Miss Eleanor V. Gildea, at Baltimore, November 4.

Deaths

John R. Buist, M.D. New York University, New York City, 1857, a member of the American Medical Association, one of the oldest and most prominent practitioners of Nashville, Tenn., and closely identified with the history of that city; for many years a member of the local and State Board of Health, regimental and brigade surgeon in the Confederate service during the Civil War, died at his home in Nashville, October 24, eight weeks after an operation performed in Rochester, Minn., aged 71. His last work was a paper on water filtration based on a study of the plant at St. Louis, which was submitted to the board of health the day before he died. In addition to his active interest in matters medical, he kept up with the times in public affairs, political, social and economic. In a special message to the city council Mayor Morris announced the death of Dr. Buist, and recommended that the council should make some recognition of his life and valuable public service.

Everett Van Buren, M.D. Rush Medical College, Chicago, 1869, formerly of Hooper, Dodge County, Neb., surgeon of the Eighth United States Colored Heavy Artillery, of the One Hundred and Forty-seventh Illinois Volunteer Infantry, and later in charge of the First Brigade Hospital, Second Division of the Army of the Cumberland in the Civil War; for six years a member of the Fremont (Neb.) city council; once vice-president of the Nebraska State Medical Society; twice coroner of Dodge County, Neb., and president of the city council of Hooper, died at the Soldiers' Home, Grand Island, Neb., October 26.

James Duane Featherstonehaugh, M.D. College of Physicians and Surgeons in the City of New York, 1870, member of the Medical Society of the State of New York, and member and once president of the Albany County Medical Society; sometime health officer and member of the board of education of Cohoes, N. Y., and surgeon to the Cohoes Hospital, died at his home in that city October 21, after an illness of a year, from malignant disease of the prostate gland, aged 60. The physicians of Cohoes, and the Albany County Medical Society, at special meetings, passed resolutions of eulogy and regard.

Edward Shelby Rauch, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1904, one of the most promising young physicians of Vicksburg, Miss., died at his rooms in the Vicksburg Infirmary from yellow fever October 20, aged 23. When yellow fever broke out at Hamburg, Miss., Dr. Rauch, believing himself immune, as he had had the disease in 1897, volunteered to aid the stricken community. After a short time, however, he was taken down with the disease, whose ravages he was not able to withstand.

Alfred Holmes Simpson, M.D. Manitoba Medical College, Winnipeg, 1894, chairman of the provincial board of health of Manitoba and professor of materia medica and therapeutics in Manitoba Medical College until compelled to resign by reason of ill-health, died at his home in Salmon Arm, B. C., October 25, aged 36.

Albert E. Warren, M.D. University of Buffalo (N. Y.) Medical Department, 1891, of Youngstown, Ohio, while despondent and suffering from renal lithiasis, for which he had undergone two operations, shot and killed himself at his father's house in Buffalo, N. Y., October 6, aged 36.

Samuel Y. Thompson, M.D. Long Island College Hospital, Brooklyn, N. Y., 1866, several times burgess of Danville, Pa., and associate judge of the Montour County Court, died suddenly at his home in Danville while writing a prescription, October 28, from heart disease, aged 62.

William C. Arons, M.D. Cincinnati, 1874, of Hudson, Wis., arrested at Colorado Springs, and under sentence of imprisonment for six years in the Minnesota state penitentiary, Stillwater, for bigamy and grand larceny, shot and killed himself in the jail at Aitkin, Minn., October 21.

Charles Edward Dever, M.D. University of Maryland School of Medicine, Baltimore, 1891, a member of the Massachusetts Medical Society and of the Lynn Medical Society, died at his home in Lynn, Mass., October 24, from cerebral hemorrhage, after an illness of thirty-six hours, aged 43.

John A. Richardson, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1884, of Ben Franklin, Texas, was shot and instantly killed in an altercation with a restaurant keeper in Paris, Texas, October 25, aged 45.

Orrin Witter, M.D. College of Physicians and Surgeons in the City of New York, 1859, representative in 1875 from his town in the General Assembly, died suddenly at his home in Chaplin, Conn., from heart disease, October 13, aged 69.

William Titus, M.D. Jefferson Medical College, Philadelphia, some-time health officer of Newark, N. J., and local surgeon for the Lackawanna Railroad, died at his home in Newark from cerebral hemorrhage October 28, aged 60.

Francena E. Porter, M.D. Woman's Medical College of Pennsylvania, Philadelphia, 1864, formerly of Worcester, Mass., died at her home in Reading Center, Mass., October 22, from heart disease, after an illness of eight years.

J. Frank Williams, M.D. Jefferson Medical College, Philadelphia, 1888, formerly of Pittsburg and Greensburg, Pa., but for three years a resident of Detroit, was struck by a train and killed near Baden, Pa., September 30, aged 42.

Anne Ceredwen Rees, M.D. Woman's Medical College of the New York Infirmary, New York City, 1898, died at her home in Union Hill, Weehawken, N. J., October 24, from double lobar pneumonia, after a short illness, aged 29.

Eleanor Chestnut, M.D. Northwestern University Woman's Medical School, Chicago, 1893, of Chicago, a missionary of the Presbyterian board in Lienchow, China, was murdered at that place October 28 by a mob in a riot.

Zachary T. Young, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1872, was shot and killed in a pistol duel with a son of a fellow-practitioner, at his home in Ville Platte, La., October 5, aged 56.

Robert J. Cummer, M.D. Cleveland Medical College Medical Department of Western Reserve University, 1880, died at his home in Cleveland October 22 from typhoid fever, after an illness of two weeks, aged 52.

George W. Emerson, M.D. Bellevue Hospital Medical College, New York City, 1864, died at his home in Webster, Mass., October 9, from degenerative spinal disease, after an illness of five years, aged 74.

James E. Miller, M.D. Bellevue Hospital Medical College, New York City, 1885, of Fort Wayne, Ind., died in St. Vincent's Hospital, Indianapolis, October 30, two days after an operation, aged 50.

James Gates Adams, M.D. University of Louisville (Ky.) Medical Department, 1882, died at his home in El Paso, Texas, October 22, from cerebral hemorrhage, after an illness of four days, aged 71.

Arthur Meriden Patterson, M.D. Ohio, 1895, of Westerville, Ohio, died at his father's home near Africa, Ohio, October 26, from laryngeal tuberculosis, after an illness of two years, aged 37.

William A. Blakeley, M.D. St. Louis College of Physicians and Surgeons, 1896, died at his home in Higginsville, Mo., October 18, from typhoid fever, after an illness of five weeks.

Thomas W. Royston, M.D. St. Louis Medical College, 1872, died at his home in Round Rock, Texas, October 25, from kidney disease, after a prolonged illness, aged 92.

Conrad Henry Disse, M.D. University of Berlin, Germany, 1853, died at his home in Nauvoo, Ill., October 21, from senile debility, after an illness of two weeks, aged 78.

Noah K. Williams, M.D. Kentucky School of Medicine, Louisville, 1889, died recently at his home in Catlettsburg, Ky., from cerebral hemorrhage and was buried October 3.

Henry Clarke Walton, M.D. Medical College of Georgia, Augusta, 1875, died at his home at Metasville, Ga., October 21, after a short illness, aged 52.

James W. Chesney, M.D. College of Physicians and Surgeons, Baltimore, 1884, died at his home in Fairmont, W. Va., October 28, from angina pectoris.

Thomas Arthur Wright, M.D. Cincinnati, 1867, died suddenly at his home in Americus, Ky., September 28, from cerebral hemorrhage, aged 64.

William J. Ward, M.D. Missouri, 1876, died at his home in Gilman, Iowa, October 4, from gastric ulcer, after an illness of six days, aged 59.

S. Gertrude Norris, M.D. Cincinnati, 1891, died at her home in Lansing, Mich., October 18, from nephritis, aged 53.

John Bryan, M.D. Ohio, 1866, died at his home in Beaver Falls, Pa., October 17, from senile debility, aged 78.

Samuel H. Wright, M.D. Geneva (N. Y.) Medical College, 1868, of Jerusalem, N. Y., died at Syracuse, N. Y., October 7, aged 80.

Franklin Shreve, M.D. Cincinnati, 1881, died at his home in Sioux Falls, S. D., October 23, after a long illness.

Deaths Abroad.

H. Schaper, M.D., for twelve years the medical superintendent of the great Berlin Charité Hospital, died October 1, aged 64. He was an army medical officer of high rank and won great distinction by his able administration of the hospital, and as member of the Imperial Board of Health, and chairman of the testing department of the pure food commission. His experience at the Charité rendered him an authority on hospital and sanitarium construction, so that his advice was sought in nearly every undertaking of the kind. He resigned his position last year on account of ill health.

R. Ruge, M.D., member of the German privy council, died at Berlin October 17, aged 71. He had long been a pioneer in matters affecting the organization of the profession, and for several years had served as a member of the city council.

E. Burckhardt, M.D., professor of surgery at Basle, died October 1, aged 52. He was an enthusiastic student of urology in relation to surgery, and published numerous works on this subject.

K. Grunert, M.D., professor of otology at Halle, died September 23, aged 38.

Miscellany

Protest Against Declaration of Diseases by Physician.—Nigay, in a signed editorial in the *Jour. de Méd. de Paris*, reviews the statistics of the notifiable diseases in France. They show that the compulsory declaration is too often a farce. The number of known cases far exceeds the number declared to the authorities. Only 37 cases of puerperal infection and 44 cases of purulent ophthalmia were declared by physicians throughout France during 1904. He proposes a radical reform—abolishing any specific declaration by the physician, but imposing on him the responsibility for all disinfections. Professional secrecy should be respected and its scope broadened, but the disinfection service should be placed entirely in his charge, to apply or not for special cases as he saw fit, doing the disinfecting himself or having it done by subordinates. The only record that he would have to turn in to the authorities would be that of the number of disinfections done day by day.

Cold Applications Better than Alcohol as Cardiac Stimulant.—The cold compress applied over the cardiac area of the chest may well replace alcohol as a heart tonic. The thing necessary to encourage the heart's action is not mere relaxation of the peripheral vessels, but, as Winternitz has shown, increased activity of the peripheral circulation in the skin, muscles and elsewhere. Alcohol paralyzes the vasoconstrictors, and so dilates the small vessels and lessens the resistance to the heart action; at the same time it lessens the energy of the nerve centers which control the heart, diminishes the power of the heart muscles, and lessens that rhythmical activity of the small vessels whereby the circulation is so efficiently aided at that portion of the blood circuit most remote from the heart. A cold application to that portion of the chest overlying the heart reflexly stimulates and energizes the heart through the cardiac nerves. This reflex action is not confined to the heart muscle; the stimulation of the activity of the cardiac vessels improves the circulation through the heart structure, refreshing and energizing it in the same manner in which a voluntary muscle is energized by a cold application, as is well shown by the ergograph.—Kellogg in *Lancet-Clinic.*

Teaching Physical Curative Measures at Medical Colleges.—Prof. W. Winternitz of Vienna contributed an article on this subject to the Congress of Physiotherapy, held at Liège last summer. He urges that physiotherapy should be an obligatory course in medical colleges, and that it should be taught clinically, not theoretically alone nor practically alone, but at the bedside, in a well-equipped clinic. The nutritional disturbance presented by the patient should first be exactly differentiated and the deviations from normal fully determined. The more exactly the nutritional disturbance is understood the clearer the indications for treatment. The test of its success will be the therapeutic experiment. The plan of treatment outlined to the students is then applied under their eyes. Successes and failures are watched, and the action of the physical measures on the innervation, circulation, blood pressure, metabolism, secretions and excretions, increase or decrease in oxidations, elimination of toxins and of morbid products, changes in the morphology and chemistry of the blood, etc., are demonstrated before the eyes of the students as the necessary consequences of the correctly dosed thermic and mechanical interventions. The young physician will then become familiar with the mode of application and of the action of these powerful curative forces, and the limitations of their field of action. The professor should be a trained clinician, convinced of the value of physiotherapy, and one semester of the obligatory internal clinic should include a course devoted to physical therapeutics.

Massage by the Blind.—In a paper read before the New York Academy of Medicine, Dr. M. B. Cotter said, according to the *Medical News*, that for several centuries the Japanese have employed blind persons to give massage and with great success. The result of this system is that massage is very well done at a comparatively cheap rate in Japan, and, as a consequence, even the poor have the opportunity to take advantage of its curative effects. The government protects the blind in their avocation from being imposed on, and thus a class of people that otherwise would be a charge on the community becomes a very useful and self-supporting element. It is easy to understand that a blind masseur or masseuse would be more acceptable for people of delicate sensibilities than a seeing one. As a rule, the blind themselves enjoy better health as a result of the exercise they obtain, and as a consequence of the interest in life aroused by a constant money-making occupation. The only place in Europe in which massage is extensively carried out by the blind is in St. Petersburg. The first teacher of it was a medical student, who became blind just before graduating. There the experience is that the blind learn rapidly, especially if the pupils are selected with the definite idea of taking only those who show special talent. It is considered that two years are needed for the proper study of anatomy and physiology in connection with massage. After graduation the students are able to find a reasonable amount of work and make a successful living. In Sweden, the home of massage, an attempt to teach the blind failed. The reason for this was said to be the absence of books with raised letters, out of which principles of anatomy and physiology might be learned. In France the blind have been used, not extensively, yet with some success. In Brussels there is a free school for the teaching of the practice of massage for the blind. In Denmark a ten-months' course is considered sufficient to prepare the blind for massage, and a reasonable amount of success has been met with in the teaching. At Brünn, in Austria, there is a successful school for the teaching of massage to the blind. The only place in Germany where a special effort has been made in this direction is at Leipsig, and here a certain amount of success has been obtained. In Philadelphia excellent work has been done in connection with the Pennsylvania Institution for the Blind at Overbrook. About a dozen graduates are making a good living out of the profession of masseur. In this country very few of the blind are self-supporting. A certain allowance is made to all blind persons by many of the states in certain cities. If this occupation could be opened up to them, a great benefit would be conferred on them, and, at the same time, massage would be made available for many more patients than at present. Dr. Charles H. Lewis said that it not infrequently happens that patients who need massage do not have it because of the expense attached to it. Many patients, for example, convalescent from typhoid fever, would reacquire their muscular energy much sooner if given massage. Few use it, however, because of the expense attached to it, in considering the large bill for medical attendance that is likely to accumulate. For many other conditions in which there is relaxation of muscular tissue, as after intestinal toxemias.

massage would add to the speed of recovery. In such conditions as pseudoparesis and in the various forms of hysterical paralysis massage would often be of the very greatest service. Always it is the expense attached to it that constitutes the main objection against its employment.

Queries and Minor Notes

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

CURES AT LOURDES.

——, ——, Oct. 26, 1905.

To the Editor:—Accounts of "Cures at Lourdes" are printed in Catholic papers, the *True Voice*, Omaha, *Catholic Standard and Times*, Philadelphia, and four or five times a year the same wonderful cures are printed. Is this a pious fraud or is it printed as facts, and do Catholics, as a rule, believe in such reports? Y.

Answer: We believe that many, if not the majority of intelligent Catholics estimate the cures of Lourdes very much as most intelligent Protestants do those of the numerous faith cures which have thrived from time to time in Protestant communities. Of course there is a certain class of people in all communions who accept them as implicitly as do the Dowieites, Eddyites, etc., the cures they report. We do not believe, however, it is an essential matter of faith, outside of these sects, to believe in modern miraculous cures of organic physical disease. The rationale of many cures in other than organic diseases is fairly well understood. The action of the Paris specialists in declining to give an opinion does not seem to us like a recognition of a supernatural fact, but rather as a declination to subject themselves to the possibility of unprofitable and annoying controversy.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending November 4.

Chidester, Walter C., asst. surg., granted leave of absence for ten days.

Woodall, Wm. P., asst.-surgeon, granted thirty days' sick leave.

Dutcher, Basil H., asst.-surg., ordered to sail for Philippine service, Jan. 5, 1906, instead of Dec. 5, 1905; granted leave of absence to include December 29.

Raymond, Thomas U., surgeon, leave of absence granted for two months.

Cowper, Harold W., asst. surg., sick leave of absence extended one month.

Robbins, Chandler P., asst.-surgeon, leave of absence granted for one month, ten days.

Williams, Allie W., asst.-surgeon, leave of absence granted for one month, ten days.

Crosby, Wm. D., surgeon, granted two months' leave of absence, to take effect on being relieved from duty in the Philippines Division, and is authorized to visit Japan.

Raymond, Thomas U., surgeon, left Fort Assinniboine, Mont., on ten days' leave.

Crampton, Louis W., deputy surgeon general, granted fifteen days' leave of absence.

Lambert, Samuel E., months' leave on being relieved from sion, with permission to return to th

Morse, Chas. F., asst.-surgeon, granted three months' leave of absence on being relieved from duty in the Philippines Division, with permission to return to the United States via Europe.

White, J. Samuel, contract surgeon, left Fort Snelling, Minn., on leave of absence for two months.

Hays, Mellville A., contract surgeon, left Vancouver Barracks, Wash., for temporary duty at Fort Wright, Wash.

Warwick, Clarence A., contract surgeon, arrived at Fort Mott, N. J., for duty.

Wythe, Stephen, contract surgeon, order for Philippine service revoked.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending November 4:

Huntington, E. O., surgeon, detached from the Navy Department and ordered home to wait orders.

Campbell, R. A., acting asst.-surgeon, detached from duty with Naval Recruiting Party No. 5, November 13, and ordered to the Naval Recruiting Rendezvous, Cincinnati.

Angeny, G. L., surgeon, commissioned surgeon with rank of lieutenant commander from April 24, 1905.

Munson, F. M., asst.-surgeon, ordered to the *Lancaster*.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending November 1:

Carmichael, D. A., surgeon, granted leave of absence for seventeen days from November 14.

Wasdin, E., surgeon, to rejoin station at Memphis, Tenn.

Magruder, G. M., surgeon, to appear before a board for physical examination, November 11, under the provisions of Paragraph 50 of the Regulations.

Guiteras, G. M., surgeon, to rejoin station at Cairo, Ill.

Gardner, C. H., P. A. surgeon, granted leave of absence for one month from November 1.

Wickes, H. W., P. A. surgeon, granted extension of leave of absence for two days, from October 28.

Greene, J. B., P. A. surgeon, to rejoin station at Fort Stanton, N. M.

Lavinder, C. H., P. A. surgeon, to rejoin station at Stapleton, N. Y.

Lavinder, C. H., P. A. surgeon, granted leave of absence for four days en route from New Orleans to New York.

Lavinder, C. H., P. A. surgeon, to report at Bureau en route to New York.

McMullen, John, P. A. surgeon, to proceed to New Orleans, and report to Surgeon J. H. White for special temporary duty.

McMullen John, P. A. surgeon, to rejoin station at Ellis Island, N. Y.

Fricks, L. D., P. A. surgeon, relieved from duty at Castries, St. Lucia, and directed to proceed to New York, N. Y., reporting arrival by wire.

Glover, M. W., P. A. surgeon, leave of absence granted him for three days from October 15, amended to read two days only.

Ward, W. K., asst.-surgeon, relieved from duty at Bridgetown, Barbadoes, and directed to proceed to New York, reporting arrival by wire.

Collins, George L., asst.-surgeon, granted leave of absence for sixteen days from October 31.

Ebert, H. G., to rejoin station at Fort Stanton, N. M.

Smith, F. C., asst.-surgeon, to rejoin station at Detroit.

Steger, E. M., asst.-surgeon, to rejoin station at Philadelphia.

Ashford, F. A., asst.-surgeon, to rejoin station at Ellis Island, N. Y., reporting at bureau en route.

McKeon, F. H., assistant surgeon, to rejoin station in New Orleans.

Frost, W. H., asst.-surgeon, to rejoin station in Baltimore.

Mullan, E. H., asst.-surgeon, to rejoin station at Ellis Island, N. Y.

Guthrie, M. C., asst.-surgeon, to proceed to Cape Fear quarantine station, reporting to the medical officer in command for duty.

Duke, B. F., acting asst.-surgeon, granted fourteen days' leave of absence on account of sickness, from October 7.

Rice, W. E., acting asst.-surgeon, granted leave of absence for seven days.

Safford, M. V., acting asst.-surgeon, granted two days' leave of absence under paragraph 210 of the regulations.

Walker, R. T., acting asst.-surgeon, granted leave of absence for five days, from November 18.

Mason, M. R., pharmacist, granted leave of absence for seven days, from October 25.

Gibson, F. L., pharmacist, to rejoin station at San Francisco, on completion of duty at Lewis & Clark Exposition at Portland, Ore.

Morris, G. H., pharmacist, to rejoin station at St. Louis.

Sterns, C. O., pharmacist, to proceed to Boston, and report to the medical officer in command for duty and assignment to quarters.

APPOINTMENT.

C. O. Sterns appointed pharmacist of the third class.

BOARD CONVENED.

A board of officers is to meet at Angel Island, Cal., November 11, to determine the physical condition of Surgeon G. M. Magruder, under provisions of paragraph 50 of the regulations. P. A. Surgeon H. S. Cumming, chairman; P. A. Surgeon F. E. Trotter, recorder. October 28.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the surgeon general, Public Health and Marine-Hospital Service, during the period from October 20 to November 4:

SMALLPOX—UNITED STATES.

California: Los Angeles, Oct. 14-21, 2 cases; San Francisco, 3 cases.

District of Columbia: Washington, Oct. 21-28, 3 cases, 1 death.

Illinois: Chicago, Oct. 21-28, 2 cases; Galesburg, Oct. 16-23, 3 cases, 2 deaths.

Michigan: Kalamazoo, Oct. 21-28, 1 case.

Ohio: Cincinnati, Oct. 13-27, 7 cases.

Washington: Seattle, Oct. 7-14, 1 case; Tacoma, Oct. 14-21, 2 cases.

Wisconsin: Milwaukee, Oct. 21-28, 1 case.

SMALLPOX—FOREIGN.

Azores Islands: St. Michael's, Sept. 16-Oct. 4, 7 cases.

Brazil: Bahia, Sept. 23-30, 1 case; Pernambuco, Sept. 1-15, 231 deaths.

Canada: Toronto: Sept. 23-Oct. 21, 15 cases.

China: Hongkong, Sept. 8-16, 1 case.

Ecuador: Guayaquil, Sept. 21-Oct. 3, 10 cases.

France: Paris, Sept. 23-Oct. 4, 28 cases, 5 deaths.

Great Britain: Liverpool, Oct. 7-14, 2 cases.

India: Calcutta, Oct. 8-23, 4 deaths; Madras, Sept. 16-29, 19 deaths.

Italy: General, Sept. 28-Oct. 5, 10 cases.

Russia: Odessa, Sept. 23-Oct. 7, 13 cases, 4 deaths.

Spain: Barcelona, Oct. 1-10, 1 death; Cadiz, Sept. 1-30, 3 cases.

Uruguay: Montevideo, Aug. 1-30, 8 deaths.

YELLOW FEVER—UNITED STATES.

Alabama: Castleberry, Oct. 15, 2 cases, 2 deaths.

Florida: Pensacola, Aug. 29-Oct. 30, 538 cases, 77 deaths.

Louisiana: Ascension Parish: to Oct. 18, 80 cases, 5 deaths; Assumption Parish, to Oct. 16, 48 cases, 2 deaths; Avoyelles Parish, to Oct. 28: 14 cases, 2 deaths; East Carroll Parish, to Oct. 18, 341 cases, 41 deaths; Iberia Parish, to Oct. 15, 14 cases, 1 death; Iberville Parish, to Oct. 13, 34 cases, 8 deaths; Jefferson Parish, to Oct. 28: 505 cases, 55 deaths; Lafourche Parish, to Oct. 19, 424 cases, 55 deaths; Madison Parish, to Oct. 28, 344 cases, 19 deaths; Natchitoches Parish, to Oct. 28, 83 cases, 7 deaths; St. Mary

Parish, to Oct. 21, 845 cases, 36 deaths; Terrebonne Parish, to Oct. 28, 334 cases, 14 deaths.

Mississippi: Gulfport, Aug. 15- Oct. 28, 120 cases, 2 deaths; Hamburg, Sept. 15-Oct. 26, 50 cases, 8 deaths; Long Beach, Oct. 18, 1 case; Mississippi City, Aug. 22-Oct. 17, 71 cases; Natchez, to Oct. 26, 142 cases, 7 deaths; Port Gibson, Sept. 27-Oct. 24, 63 cases, 2 deaths; Rosetta, to Oct. 17, 32 cases, 7 deaths; Roxie (vicinity of), to Oct. 26, 16 cases, 1 death; Vicksburg and vicinity, Aug. 30-Oct. 30, 176 cases, 26 deaths.

Ohio: Cincinnati, Sept. 15-19, 3 cases.

YELLOW FEVER—FOREIGN.

Cuba: Habana, Oct. 16, 1 case, on S. S. *Vigilancia.*

Ecuador: Guayaquil, Sept. 28-Oct. 3, 1 death.

Guatemala: Livingston, Oct. 18, 1 case.

Honduras: Choloma, Oct. 3-17, 3 cases, 1 death; Puerto Cortez, Sept. 26-Oct. 3, 1 death; San Pedro, Oct. 3-17, 5 cases.

Mexico: Omealca, Oct. 8-21, 12 cases, 1 death; Soconusco, 3 cases, 2 deaths; Tuxtepec, Oct. 8-21, 19 cases, 9 deaths; Vera Cruz, 5 cases, 5 deaths.

Panama: Colon, Oct. 4, 1 case removed from Matachin; Bocas del Toro, Oct. 6, 1 case.

CHOLERA—INSULAR.

Philippine Islands: Laguna province, Sept. 8-16, present in two localities; Manila: Sept. 8-23, 32 cases, 31 deaths; Rizal Province, Sept. 8-16, present in 8 localities.

CHOLERA—FOREIGN.

India: Bombay, Sept. 19-Oct. 3, 4 deaths; Calcutta, Sept. 9-23, 75 deaths; Madras, Sept. 16-29, 349 deaths.

PLAGUE—INSULAR.

Hawaii: Honolulu, Oct. 23-24, 3 deaths.

Philippine Islands: Manila, Sept. 16-22, 1 case, 1 death.

PLAGUE—FOREIGN.

Argentina: Choya, Sept. 10, 9, recrudescence.

Australia: Townville, Sept. 8-16, 2 cases, 2 deaths.

China [illegible] 8-23, 1 case, 2 deaths; Manchuria, Oct. 4, [illegible] Oct. 17, 3 deaths.

India [illegible] 3,439 cases, 2,482 deaths; Bombay, Sept. 9-23, 72 deaths; Karachi, Sept. 17-Oct. 1, 33 cases, 32 deaths.

Peru: Lima, Sept. 11-29, 8 cases, 1 death; Payta, 6 cases, 3 deaths; Mollendo, 1 death.

Society Proceedings

COMING MEETINGS.

Southern Surgical and Gynecological Association, Louisville, Ky., Dec. 12-14.

American Dermatological Association, New York, Dec. 28-30.

Western Surgical and Gynecological Association, Kansas City, Mo., Dec. 27-28.

MEDICAL SOCIETY OF VIRGINIA.

Thirty-sixth Annual Session, held in Norfolk, Oct. 24-27, 1905.

The President, Dr. William S. Christian, Urbana, in the Chair.

A brief address of welcome was delivered by Judge D. Tucker Brooke, which was responded to by Dr. Lewis G. Pedigo, Leatherwood, for the society.

The Line of Least Resistance.

Dr. Paul B. Barringer, Charlottesville, chairman of the faculty of the University of Virginia, delivered an address on some of the adverse conditions which confront a medical man in the practice of his profession. He said it is well known in the profession that a physician can not do his best work when unusual influences and disturbing factors are around him, and that this was one of the reasons operating against those who, like President Garfield or President McKinley, were treated, so to speak, in the light of public gaze. Under such conditions a physician may lose his nerve under his sense of responsibility. The chances of the pauper picked up on the street and carried to the hospital for immediate operation are, therefore, better than those of the more prominent man. He suggested that it is much better for the friends of the patient to refrain from asking questions until the doctor is ready to give information. In families of physicians little medicine is usually administered and nothing is ever done until an accurate diagnosis has been made. He alluded to the imperative duty resting on the physician to report to the local board of health any cases of communicable disease and commented on the warning that may be seen in the experience in New Orleans with yellow fever. With the advanced knowledge of the present day there should never be a return of the plagues which, in past history, have devastated continents.

The Country Doctor.

Dr. William S. Christian, Urbana, the president, in his annual address, stated that he had been a country doctor for fifty-four years, that the country practitioner must be a good all-around man, a good student of human nature and acquainted with the inner life and characteristics of his people. He treats all classes of cases and many diseases which, in cities, would be divided up among several classes of specialists. He maintained that, in ordinary diseases, the country doctor is more accurate in diagnosis than his city brother, that he has more time for this work and that, being his own apothecary, he can compound his prescriptions, administer them to the patients and observe the results. The life of the country doctor is full of hard and laborious toil, but, although he is the most poorly paid man in the world, he finds a rich reward in the love of his people.

Nephritis.

The medical aspect of nephritis was discussed by Dr. James S. Irwin, Danville, and the surgical aspect by Dr. Hugh M. Taylor, Richmond. The fact most clearly brought out in the papers and discussion was the curability of nephritis; that if the disease be taken in its earliest stages, the patient stands a good chance of recovery. Much progress has been made in the treatment of the disease, and individual symptoms are now receiving more attention than heretofore.

Bubonic Plague.

Dr. Thomas R. Marshall, Bedford City, late chief health inspector of the Philippine Islands, and a member of the board of health of the Philippine Islands and the city of Manila, who is now in the United States on leave, read an important paper on bubonic plague, in which he stated that the spread of the plague could be controlled by a system of inoculation. In the Philippines 30,000 persons have been immunized by the prophylactic serum manufactured in the government laboratory at Manila, and none of these persons has contracted the disease, although exposed to it after immunization.

Admission of Non-graduate Practitioners.

A considerable discussion arose on the question of the admission of practicing physicians of the state who did not possess diplomas from recognized medical colleges. During, and just after the Civil War, when it was extremely difficult to secure a college medical education, a number of men studied medicine under recognized practitioners and are now permitted to practice, although holding no diplomas, and are rated among the best regular and general practitioners of the state. Several of these men have applied for membership in the society, the laws of which provide, as a requisite for membership, that an applicant must be a graduate of a reputable school of medicine. The society, however, by an overwhelming majority, agreed to suspend the rules and to admit all such practitioners.

Asks Repeal of State Tax.

The society decided to petition the legislature to repeal the state license fee of $10 which is now imposed on physicians.

Entertainment.

The social features of the convention were a banquet on the first day for the members of the society; a trip on the steamship *Pennsylvania* around the harbor on the second day; at the close of the convention a trip to Cape Henry and an oyster roast, and, in addition, a number of private entertainments and receptions by the local profession.

Election of Officers.

The following officers were elected: President, Dr. Lomax Gwathmey, Norfolk; vice-presidents, Drs. S. T. Anderson Kent, Ingram; Greer Baughman, Richmond, and Tunis C. Quick, Falls Church; recording secretary, Dr. Landon B. Edwards, Richmond (re-elected); corresponding secretary, Dr. John F. Winn, Richmond (re-elected); treasurer, Dr. Robert M. Slaughter, Theological Seminary; executive committee, Drs. Paulus A. Irving, Moses D. Hoge and Clifton M. Miller, Richmond; William F. Drewry, Petersburg, and Frank H. Hancock, Norfolk; state medical board—first district, Dr. Willard B. Robinson, Rappahannock; second district, Dr. Herbert M. Nash, Norfolk; third district, Dr. Junius E. Warinner, Brook Hill; fourth district, Dr. William W. Wilkinson, La Crosse; fifth district, Dr. Richard S. Martin, Stuart; sixth district, Dr. Samuel Lile, Lynchburg; seventh district, Dr. Robert C. Randolph, Boyce; eighth district, Dr. Robert M. Slaughter, Theological Seminary;

ninth district, Dr. Elliott T. Brady, Abingdon; tenth district, Dr. Charles W. Rodgers, Staunton; at large, Drs. Rawley W. Martin, Lynchburg; A. S. Priddy, Bristol, and R. Bruce James, Danville; delegate to American Medical Association, Dr. William E. Anderson, Farmville; honorary fellows, Drs. William S. Christian, Urbana, and Robert G. Halloway, Port Royal; non-resident honorary fellow, Dr. George Tully Vaughan, assistant surgeon general United States Public Health and Marine-Hospital Service, Washington, D. C.

Charlottesville was selected as the next place of meeting.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Regular Meeting, held Sept. 7, 1905.

Dr. Wilmer Krusen in the Chair.

Mercurialism from Bichlorid Douche.

Dr. Frank C. Hammond reported a number of cases, in one of which severe mercurialism occurred, due to excessive use of very strong bichlorid vaginal douches given to produce an abortion. The uterus was curetted for incomplete abortion. During the first six days, after symptoms of mercurialism appeared, only five ounces of urine were secreted, secured by catheterization.

DISCUSSION.

Dr. J. W. West said that it is of the greatest importance in the treatment of obstetric cases, in which one is dependent on untrained nurses, to give careful instructions about all douches and enemata that are to be used. He recalled two experiences where untrained nurses substituted 1/1000 bichlorid solution for soap and water for rectal injections. One of the women was so desperately ill for a number of days that her life was despaired of, although there was ultimate recovery. These experiences led him to emphasize that we can not be too careful about instructions when having untrained assistants.

Aseptic Management of the Umbilical Cord.

Dr. J. Thompson Schell advocated the method of Dr. Dickinson of Brooklyn and Dr. C. S. Bacon of Chicago, as follows: When the child is delivered a hemostat is placed on the cord three inches from the abdominal wall and a second hemostat about one inch from the first, and the cord severed between. The child is laid to one side, wrapped in its receiving blanket, while the placenta is delivered and the mother attended to. The attention is now directed to the child and the cord is amputated as follows: Grasp the hemostat forceps in one hand and with a sharp-pointed scissors the cord is severed at its skin-amniotic junction and the amniotic covering and Wharton's jelly is then separated from the vessel of the cord by stripping them back with a piece of gauze in a direction away from the abdominal wall. The vessels are now ligated with a piece of No. 0 sterile catgut and the cord is dusted with an antiseptic powder. The baby is not placed in the tub for about ten days. Dr. Schell has never had a case of umbilical hernia in babies on which the cord has been tied off in this way. The hernias he has seen have occurred in children who have been sick after delivery with marasmus, pneumonia, or some illness causing them to cry. In these cases hernia would probably have resulted without regard to the method of treating the stump. Hernias occur less often with this method than with the older ones. The ring is stronger when it is clean than when infected. He has nipped the vessels several times, but has never had any trouble. Although they would bleed for a moment the bleeding was so slight that he did not put a ligature around the vessels, except as a precautionary measure. He has never seen hemorrhage that he would call frightful. In making this incision he has cut the vessels a number of times, but has never had any trouble. He simply throws the ligature a little further back. The only bad case of hemorrhage occurred on the eighth day. There was a polypoid-like growth on the end of stump and the vessels must have bled from that and insertion of pins was necessary. Recovery finally ensued, but later symptoms of general infection set in. Many obscure illnesses in young infants probably result from an infected stump, and childbed fever in the mother may be traced to the same source.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Arteriosclerosis.

Professor Romberg, in the *Deutsche medizinishe Wochenschrift*, in an article on the treatment of this disease, says that when the heart is mainly affected the coronary vessels may be the first to become sclerosed, and this may give rise to definite symptoms of cardiac insufficiency. The old remedy for this was digitalis which, of course, should not be given in cases in which there is actual or threatened hemorrhage. Sawada, however, has shown that in cases of arteriosclerosis, without involvement of the kidneys, the arterial tension is not high, and digitalis in small doses may be given with good results. Groedel's method of giving 2 grains of freshly powdered digitalis leaves once or twice a day for a prolonged period is particularly recommended. For long continued use strophanthus may also be of value. In plethoric individuals it is better to follow Huchard's advice and to enjoin strict milk diet for five days, combined with the use of digitalis. In angina pectoris digitalis is indicated only in the slight cases in which cardiac weakness is obvious between the attacks. In severe cases with normal cardiac power it is useless. In cardiac asthma, especially nocturnal, a narcotic with camphor or caffein is recommended, but morphin is contraindicated in angina pectoris. The author has found the inhalation of amyl nitrite of little use in severe cases. When cardiac weakness from coronary sclerosis is combined with abdominal plethora the arterial pressure is often raised. In such cases purgation is valuable. When the kidneys are affected early, severe and sudden breathlessness is often a conspicuous sign; the pulse tension is increased, and if the heart is feeble the amount of urine is normal or diminished. Here also the indications are for general depletion and cardiac tonics. Digitalis must be used with the utmost caution, as in severe cases it may even reduce the arterial tension. Any heart weakening procedures, such as powerful diaphoresis or an exclusively milk diet, are to be avoided.

When the cerebrum is mainly affected there are certain functional cerebral manifestations apart from hemorrhage and from thrombosis, which betoken intracranial arteriosclerosis. These are more especially a sense of weight in the head, a feeling of precordial oppression and sleeplessness; there may also be slight vertigo, tinnitus, and gastrointestinal disturbance. The patients are often irritable and excitable, while their mental acumen and memory for recent events diminishes. The onset of these neurasthenic symptoms after the age of 40, and especially of 50, should be regarded with suspicion. Special points in the treatment are removal from customary surroundings, attention to the digestion, frequent nourishment and the consumption of a considerable quantity of water. This last remedy lessens discomfort and helps sleep. Gastrointestinal symptoms may occur in severe paroxysms, which yield best to atropin. Vascular neuroses of various types are common complications. The first indication is to reduce the vascular excitability; this is best done by the mild local baths recommended by Erb. Excitant baths are inadvisable. The best drugs are quinin, potassium bromid and valerian.

For the general treatment of arteriosclerosis Romberg states that the best remedy is potassium iodid, which he believes acts by reducing the viscosity of the blood and so lessens the work to be done by the vascular system. It is not to be given when there is edema of the lungs or when the arteriosclerosis is complicated by Graves' disease. It should be administered to the extent of not more than 15 grains a day, in five doses, and its use should extend, with intermissions, over two or three years.

In order to minimize gastric disturbance it can be given with sodium bicarbonate, and acid foods are to be avoided. For cerebral arteriosclerosis a mixture of sodium bicarbonate, sodium nitrite and potassium nitrite is recommended. Of great importance is the regulation of the patient's habits. Arteriosclerosis is regarded as a nutritional affection of the vessel wall resulting from wear and tear; unless syphilis be present a direct remedial action of drugs on the process is not to be expected. It is essential, therefore, that any source of added strain on the vascular system be avoided. Hence, physiologic rest is indicated; obesity, for instance, should be reduced by diet and not by exercise. Sleep is also an important necessity and it may be advisable to give a hypnotic for three or four nights, after which natural repose is established. Indifferent and brine baths are useful, but must not be too hot nor too cold. The use of alcoholic liquors, tea, coffee and tobacco is to be restricted, though small quantities may be allowed as stimulants to the appetite. Abstinence from tobacco is compulsory in angina pectoris. With regard to diet, each case is treated individually, according to the state of nutrition and the condition of the alimentary canal; a mixed diet with very little condiment and not too much meat is generally advisable. Plenty of fluid should be taken, and sudden changes of diet avoided. The remedies for arteriosclerosis are essentially mild ones; the two chief lines of treatment to avoid are, on the one hand, a procrustean rule, and on the other, too frequent and fussy interference.

Exophthalmic Goiter.

Rudolf, in the *Dominion Medical Monthly*, discusses the medical treatment of this condition and states that the disease tends to recovery. In the absence of any specific treatment, he says, the following indications obtain and Nature is aided in her effort to overcome the disease:

1. To prevent the excessive production of thyroid secretion, or to neutralize the poisonous amount of it that is circulating in the blood.

2. To treat the symptoms as they arise.

To meet these indications the author summarizes his treatment as follows:

1. First and most important, the patient should be placed in a state of physical, mental and emotional rest. If the case be at all acute the patient would better be kept entirely recumbent, as the upright position will greatly hasten the heart's action. As a rule these patients do better away from home, either in a hospital or sanitarium. In some cases the strict régime of Weir Mitchell is advisable.

2. By careful dieting and in every way possible the general health should be raised; anemia, constipation and every other deviation from normal must be attended to. Very few patients with exophthalmic goiter die from the disease itself, death, when it occurs, being due to some intercurrent affection—hence the special need of looking after the general health. The climate at a moderate elevation seems to be specially beneficial, and such a location should be chosen whenever possible. Nothnagel considers "a sojourn in a place of moderate elevation as most important."

3. Various local applications may be employed, such as pressure to the thyroid gland, or a mild galvanic or faradic current, but probably the most valuable local treatment is application of cold to the thyroid gland or to the precordium, either in the form of an icebag or as Leiter's tubes. Such use of cold often greatly controls the rapid action of the heart.

4. Medicinal remedies will vary greatly with the physician, nearly every man has some remedy which he especially relies on; which fact proves what a secondary place all drugs take in the treatment of this condition. Rudolf gives a mixture of belladonna (from 10 to 15 minims of the tincture), thrice daily, combined with strontium bromid, and feels convinced that the patients soon feel very much more comfortable.

5. Any special symptom, such as threatened heart failure, urgent diarrhea, etc., must be met with appropriate remedies. Under such hygienic and medicinal treatment most patients will slowly improve, and some will completely recover. The majority, however, will retain some traces of the disease, such as cardiac irritability, general nervous instability and some exophthalmos. The disease is a prolonged one, and the patient requires much patience and all the encouragement that the attendant can give. The latter should resort to mental therapeutics as much as possible.

Gastralgia.

Shoemaker, in the *New York Medical Journal*, relates the following cases:

The patient had a history of frequent attacks of pain in the epigastrium, agonizing in character and reflected around the lower portion of the ribs. The seizure occurred more frequently when the stomach was empty and lasted for ten or fifteen minutes. The examination of the patient was negative except that the stigmata of hysteria were present. Dr. Shoemaker suggested hyosein hydrobromid in 1/100 grain doses during the attack, though the drug was not to be given as a routine practice. In less severe attacks the following combination was advised:

℞.	Spts. chloroformi	ʒiv	16|
	Spts. ætheris compositi	ʒvi	24|
	Tinct. capsici	ʒi	4|
	Aquæ dest., q. s. ad	℥iii	90|

M. Sig.: One teaspoonful in water every half-hour until relieved.

As the patient was anemic she was given the following for this and the general nervousness:

℞.	Ext. sumbul.	gr. xx	1|30
	Zinci valerianatis	gr. xxx	2|
	Ferri reducti	gr. xx	1|30
	Ext. nux vom	gr. vii	|5

M. Ft. cap. No. xx. Sig.: One capsule four times a day.

Medicolegal

Prescribing When Drunk.

Section 365 of Chapter 169 of the Laws of Indiana of 1905, an act concerning public offenses, provides that whoever, while in a state of intoxication, prescribes or administers any poison, drug or medicine to another, which endangers the life of such other person, shall, on conviction, be fined not less than $10 nor more than $100, and be imprisoned in the county jail not less than ten days nor more than three months.

Prescribing Secret Medicines.

Section 366 of Chapter 169 of the Laws of Indiana of 1905 provides that whoever prescribes any drug or medicine to another, the true nature and composition of which he does not, if inquired of, truly make known, but avows the same to be a secret medicine or composition, and thereby endangers the life of such other person, shall, on conviction, be fined not less than $30 nor more than $100, and be imprisoned in the county jail not less than sixty days nor more than six months.

To Instigate Masturbation Is Sodomy.

Section 473 of Chapter 169 of the Laws of Indiana of 1905 provides that whoever commits the abominable and detestable crime against nature with mankind or beast; or whoever entices, allures, instigates or aids any person under the age of 21 years to commit masturbation or self-pollution, shall be deemed guilty of sodomy, and, on conviction, shall be fined not less than $100 nor more than $1,000, to which may be added imprisonment in the state prison not less than two years nor more than fourteen years.

Prohibits Careless Distribution of Drugs.

Chapter 33 of the General Laws of Minnesota of 1905 provides, under penalty, that no person or persons, either directly or indirectly, by agent or otherwise, shall scatter, distribute or give away any samples of any medicine, drugs or medicinal compounds, salve or liniment of any kind unless the same is delivered into the hands of an adult person, or mailed to such persons through the regular mail service.

Wood Alcohol to be Specially Marked.

Chapter 35 of the General Laws of Minnesota of 1905 provides, under penalty, that no person, by himself, his servant or agent, or as the servant or agent of another person or persons, shall sell, exchange, deliver or have in his custody or possession with intent to sell, exchange or deliver, or expose or offer for sale, exchange or delivery, any wood alcohol, or substance commonly known as wood alcohol, unless each package, bottle, cask, can or receptacle containing the said wood alcohol shall be plainly marked, stamped, branded or labeled on the outside and face of each package, bottle, cask, can or receptacle of the capacity of less than one gallon, in legible type not smaller than large primer, and on the outside and face of each package, bottle, cask, can or receptacle of the capacity of one gallon or more, in legible letters of not less than one inch in length, the letters and words "wood naphtha," "poison."

Soliciting and Advertising Abortifacients.

Section 368 of Chapter 169 of the Laws of Indiana of 1905 provides that every woman who shall solicit of any person any medicine, drug or substance or thing whatever, and shall take the same, or shall submit to any operation or other means whatever, with intent thereby to procure a miscarriage, except when done by a physician for the purpose of saving the life of mother or child shall, on conviction, be fined not less than $10 nor more than $500, and be imprisoned in the county jail not less than thirty days nor more than one year; and any person who, in any manner whatever, unlawfully aids or assists any such woman in the violation of this section shall be liable to the same penalty.

Section 465 provides that whoever prints or publishes any advertisement of any secret drug or nostrum purporting to be for the exclusive use of females, or which cautions females against their use when in a condition of pregnancy, or in any way publishes any account or description of any drug, medicine, instrument or apparatus for preventing conception or for procuring abortion or miscarriage, or sells or gives away, or keeps for sale or gratuitous distribution any newspaper, circular, pamphlet or book containing such advertisement, account or description, or any secret drug or nostrum purporting to be exclusively for the use of females, or for preventing conception or procuring abortion or miscarriage, shall be fined not less than $5 nor more than $500, to which may be added imprisonment in the county jail not less than ten days nor more than six months.

Restrictions on Sale and Prescription of Cocain.

Chapter 42 of the General Laws of Minnesota of 1905 provides that no person shall sell or give away any cocain, hydrochlorate or any salts or compound of cocain, or preparation containing cocain, except on the written prescription of a physician or dentist licensed under the laws of the state. No prescription containing cocain shall be filled more than once and each shall have written plainly on it the name and address of the patient and be filed and preserved by the pharmacist, who shall not give a copy thereof to the patient. This section shall not be so construed as to apply to sales at wholesale, in original packages, by any manufacturer or wholesale dealer, to a retail druggist, licensed physician or dentist when such vendor shall have affixed to each receptacle containing any such drug a label in the English language specifically setting forth the proportion of cocain contained therein.

Any person who shall sell or give away any of the articles mentioned in the preceding section, in violation of this act, and any person who shall prescribe any of such articles to any one addicted to the habitual use of cocain or any preparation or compound thereof in any form, shall be punished by a fine of not less than $50 nor more than $100, or by imprisonment in the county jail for not less than thirty days nor more than ninety days, and if the person so offending shall be a licensed physician, dentist, pharmacist, or assistant pharmacist, in addition to the penalty above described, such offender's license shall be revoked.

On complaint being made of the violation of the provisions of this act the county attorney of the county where the offense is alleged to have been committed shall prosecute such complaint and to that end is hereby authorized to examine the books of any manufacturer or wholesale dealer within the state for the purpose of tracing the sales of any of the articles herein mentioned.

Physicians from Other States in Minnesota.

Chapter 236 of the General Laws of Minnesota provides that the state medical examining board, either with or without examination, may grant a license to any physician licensed to practice by a similar board of another state, and who holds a certificate of registration showing that an examination has been made by the proper board of any state in which an average grade of not less than 75 per cent. was awarded the holder thereof, the said applicant and holder of such certificate having been at the time of said examination the legal possessor of a diploma from a medical college in good standing in this state, which said diploma may be accepted in lieu of an examination as evidence of qualification. In case the scope of said examination was less than that prescribed by this state the applicant may be required to submit to an examination in such subjects as have not been covered. The fee for such examination shall be $50.

A certificate of registration or license issued by the proper board of any state may be accepted as evidence of qualification for registration in this state, provided the holder thereof was at the time of such registration the legal possessor of a diploma issued by a medical college in good standing in this state and that the date thereof was prior to the legal requirements of the examination test in this state.

If by the laws of any state or the rulings or decisions of the appropriate officers or boards thereof, any burden, obligation, requirement, disqualification or disability is put on physicians registered in this state or holding diplomas from medical colleges in this state which are in good standing therein, affecting the right of said physicians to be registered or admitted to practice in said state, then the same or like burdens, obligations, requirements, disqualifications or disability shall be put on the registration in this state of physicians registered in said state or holding diplomas from medical colleges situated therein.

1 *Study of Certain Complications and Sequels Met in Operative Cases of Laryngeal Diphtheria. B. F. Royer, Philadelphia.
2 *Frequency and Etiology of Acute Non-Tuberculous Pneumonia in a General Hospital. W. T. Howard, Jr., Cleveland, Ohio.
3 *Consideration of Hyperchlorhydria. J. A. Lichty, Pittsburg, Pa.
4 *Treatment of Hyperacidity and Hypersecretion of the Stomach. A. Albu, Berlin, Germany.
5 Insomnia and Its Treatment. J. S. Christison, Chicago.
6 *Series of Experiments to Determine the Antitoxic Depreciation of Antidiphtheric Serum. L. C. Layson, Detroit, Mich.

1. Complications and Sequels of Laryngeal Diphtheria.—Royer discusses the complications immediately following intubation, or attempts to intubate, when, from reflex apnea, cardiac or respiratory disturbances occur, of such gravity as to compel one to modify the procedure, or of such serious type as to cause the death of the patient. Royer states that atony of the cricoarytenoidei postici muscles may be a cause of acute stenosis after extubation. He also emphasizes the fact that reflex apnea causes dangerous disturbances. Atony of the abductors causes a tube to be returned in many instances. Pressure paralysis and exhaustion of adductors frequently cause autoextubation. Retained tubes are also caused by pathologic changes in the soft structure of the larynx and trachea. Such changes are often hypertrophic in character, following traumatism from the tube or loss of tissue from disease. There may be new cartilage formation in the perichondrium narrowing the lumen of the larynx, thus making a distinct pathologic change. For reflex apnea but little can be done. The courses of treatment open for the other conditions are: (1) Persist with intubation; (2) insert large tubes, allowing them to remain for long intervals of time; (3) when autoextubation becomes dangerous and large tubes are not retained, do tracheotomy; (4) intubate frequently while wearing the tracheotomy tube in order to prevent stricture stenosis; (5) with chronic stenosis due to contracting scar tissue, practice wide dilation with persistent intubation; (6) consider Roentgen-ray treatment as a possible adjunct in softening scars causing chronic stenosis; and (7) avoid, if possible, tracheotomy as a means of curing a patient of a tube habit.

2. **Acute Non-tuberculous Pneumonia.**—Howard's study is based on a series of 550 consecutive autopsies. All doubtful cases and all cases of simple bronchitis are excluded. The diagnosis in every case was based on microscopic, as well as on macroscopic examination. The 550 cases furnish 195 instances of acute non-tuberculous pneumonia, an incidence of 35.45 per cent. Of this number 35 were primary pneumonias, 31 cases of acute croupous pneumonia and 4 cases of acute bronchopneumonia. One hundred and sixty cases were secondary pneumonias, 36 cases of acute croupous pneumonia and 124 cases of acute bronchopneumonia. Seventy-six, or about 61 per cent. of these cases, occurred in individuals with acute infectious processes. Of the 43 autopsies in typhoid fever cases in this series, 22 of the subjects had had bronchopneumonia and 5 croupous pneumonia. Of 81 cases of peritonitis from all causes, 36 of the subjects, or 44.4 per cent., had had pneumonia. A study of these cases does not indicate that operation in peritonitis increases the incidence of pneumonia. This point, however, needs further study. In all cases of diphtheria and pertussis coming to autopsy, there had been pneumonia. There were no autopsies in cases of scarlatina, measles or variola. Individuals with chronic nephritis and arteriosclerosis are apparently more likely to have croupous than bronchopneumonia as a terminal infection. Thus of 36 cases of secondary croupous pneumonia, arteriosclerosis was the most marked chronic lesion in 10 and chronic nephritis in 3, while of 124 cases of secondary bronchopneumonia, arteriosclerosis was the most marked lesion in 12, and chronic nephritis in 3.

3. **Hyperchlorhydria.**—According to Lichty, about one-half of the patients suffering from digestive disturbances have hyperacidity. Many cases of neurasthenia, hysteria, melancholia and hypochondriasis, and some of the organic nervous diseases, such as tabes dorsalis, are frequently associated with hyperacidity. The same thing is true of gastric ulcer and diseases of the gall bladder and bile ducts. The anatomic lesions in hyperchlorhydria are not constant. In some cases there is a proliferation of the glandular element, while in others there is no change whatever. Lichty is of the opinion that hyperchlorhydria proper is always associated with a neurotic condition, and that those cases in which there is a hyperacidity and no associated neurotic condition belong to that group of cases manifesting the earliest stage of chronic gastritis. Proper and timely treatment, says Lichty, is followed in a surprisingly short time by entire recovery. In conclusion, he emphasizes the following points: (1) Hyperacidity is a frequent condition. (2) Hyperchlorhydria is difficult to diagnose. The diagnosis can not be made without an analysis of the stomach contents, and often must be withheld until the course of the condition can be observed. (3) The treatment must be persistent. (4) The prognosis, so far as relief of symptoms is concerned, is good; so far as overcoming the acidity, it is unfavorable.

4. **Hyperacidity.**—Albu says that in hyperacidity the treatment must be chiefly dietetic, not only in the negative sense, forbidding sour foods, sauces and drinks, spices and other stimulants, alcohol, etc., but in a positive sense by prescribing a very detailed diet. The ingestion of drinks and liquid foods should be limited to a minimum. Solid foods should be taken in the form of broths, single portions of food being given in as small quantities as possible at intervals of from one to two hours.

6. **Depreciation of Antidiphtheric Serum.**—Layson bases his paper on a laboratory study of antidiphtheric serum representing the stock from which the market had been supplied, together with samples returned from the market, all kept under the varying conditions encountered by field antitoxin. He concludes that the antitoxic value of antidiphtheric serum is retained much longer than has hitherto been believed. The majority of diphtheric serums retain their antitoxic potency unimpaired or but slightly diminished for two, three, four or even five years, and that the maximum depreciation of the occasional serum does not exceed 33.3 per cent., which contingency is guarded against in the practice prevalent with American mercantile antitoxin establishments of adding an excess of serum sufficient to cover the loss sustained by the occasional sample.

Medical Record, New York.

October 28.

7 **Observations on the Cause and Treatment of Perineal Abscess and of the Periurethral Suppurations above the Triangular Ligament.* S. Alexander, New York.
8 *Indications for Operating in Acute Mastoiditis. P. D. Kerrison, New York.
9 *Convalescents; Their Care from the Medical Standpoint. L. K. Frankel, New York.
10 *Treatment of Typhoid Fever. D. E. English, Millburn, N. J.

7. **Perineal Abscess and Periurethral Suppurations Above the Triangular Ligament.**—Great stress is laid by Alexander on the origin of these two conditions in certain cases from infections extending into the glands of Littré, the glands of Cowper, the accessory glands found in the bulb of the corpus spongiosum and in the prostate gland. He says that at present the view is accepted that perineal abscess is due to a microbic invasion from the urethra, which occurs in three ways: (1) Through the glands connected with the bulbous, membranous or prostatic urethra, from which it extends into the perineal tissues; (2) it may occur through small fissures in the mucous membrane of the urethra; (3) it may be the result of a more or less extensive mechanical rupture of the urethra from external or internal violence. Infiltration of urine may occur and may play a prominent part in the infection, or it may be absent. It is not an essential causative factor in these cases. The essential cause of perineal abscess is the action of some pathogenic microbe, but contributing and exciting causes are external injuries, such as falls or blows, and especially by the unskillful or ill-advised use of urethral injections and irrigations, and rough and unnecessary instrumentations. Alexander, therefore, warns against irrigating the deep urethra, except through a catheter, or forcible injections. He considers that perineal suppurations of urethral origin can not be efficiently treated except by operation, and summarizes his plan of treatment as follows: An abscess in the perineum should be freely opened by median incision and its cavity thoroughly disinfected; the membranous urethra should also be opened, and the deep urethra should be explored by the finger, to detect any foci of suppuration which may be present either about the membranous urethra or in the prostate. When such foci are found they should be opened by the finger into the urethra, and the floor of the abscess should be made level with the floor of the urethra; the urine should be diverted from the urethra for a few days by draining the bladder through a large catheter passed into the perineal wound. The details of the operation are described at length and reports of nine cases managed in this way are given.

8. **Indications for Operating in Acute Mastoiditis.**—Kerrison summarizes the indications for operation as follows: (1) Sudden cessation of the aural discharge, other symptoms persisting, with deep-seated pain in mastoid region. Marked sensitiveness to pressure on the mastoid over an area extending well beyond the limits of the antrum. (2) In the absence of fever, the above symptoms, unless yielding promptly, i. e., in from twenty-four to forty-eight hours, to abortive measures. (3) Marked tenderness over the antrum, persisting from four to five days after free incision of Shrapnel's membrane. (4) Marked variations in the quantity of pus discharged; its maximum flow being apparently too great to be explained by the tympanic lesion; its period of diminution being coincident with the development of mastoid pain or tenderness. (5) Mastoid tenderness having been present and having disappeared, a discharge from the tympanic vault, which resists all rational nonoperative measures. (6) Finally, evidences of mastoid involvement having been present, the development at any time during convalescence of symptoms of septic absorption.

9. **Care of Convalescents.**—Frankel says that notwithstanding the strides that have been made within the past two decades, in sanitary science, in the practice of medicine and surgery, in the betterment of living conditions, and in the general improvement in the physical status of all classes of the population, it is nevertheless a fact that in only a few diseases has

the death rate been lowered. A study of the census reports shows that while deaths from cholera infantum, diphtheria and consumption were less in 1900 than in 1890, the reverse was the case for nearly all other diseases. This state of affairs the author attributes largely to the fact that in hospital work and in private practice among the lower classes it is impossible for economic reasons to keep the patients under treatment until they are fully restored to health and strength, and in this way a large class of "half-cured" people is developed. These are in a condition of lowered vital resistance so that they easily fall a prey to serious illnesses. The remedy lies in the establishment of suitable convalescent homes, which shall not be like hospitals, but shall resemble as nearly as possible the normal home. For this purpose the country is most suitable, and where land is cheap such institutions should be built on the cottage plan. At the same time, the patient's family must be provided for in his absence, and in this connection the author speaks of the Winifred Masterson Burke Relief Foundation and the Loeb Memorial Home for Convalescents. He urges that the benevolent work of these private institutions be taken up by the state, and says that this would be the best prophylactic against disease of all sorts.

10. **Carbolated Camphor in Typhoid.**—English outlines his plan of treatment, in which the first step, if the patient is seen before the end of the first week, consists in the administration of from ten to twenty or even thirty grain of calomel, followed in eight hours by half an ounce of magnesium sulphate. The diet consists of Weir Mitchell's beef juice, and egg albumin water; milk and toast being avoided, as the author regards these two foods as being particularly harmful. The special medicinal treatment is by means of carbolated camphor, consisting of three parts of gum camphor to one part of crystallized carbolic acid liquified by heat. The dose is from ten to twelve drops in capsules, at first every two hours and later less often as the fever declines, the abdominal symptoms improve or cardiac depression appears. With this treatment English says that the course of the disease is shortened and the mortality lessened.

14 *Transplantation of the Round Ligaments for the Correction of Backward Displacements of the Uterus. E. W. Pinkham, New York.
15 Hodgkin's Disease with a Milky, Non-fatty Pleural Effusion (concluded). D. L. Edsall, Philadelphia.
16 Clinical and Operative Reports of Cases of Biliary and Pancreatic Calculi. E. Staehlin and W. J. Roeber, Newark, N. J.
17 Treatment of Hay Fever. L. W. Sterne, New York.

14. **Operative Treatment of Retrodisplaced Uterus.**—Pinkham has devised an operation which he describes as follows: A curved transverse incision is made after the method of Stimson and Hartley, passing through two points just above the external rings, and carried up on each side about one inch from these points. The skin is then dissected back from the fascia for some distance, the round ligaments are sought for as in the Alexander operation, the accompanying nerves are separated, and the enfolding peritoneum is pushed back until about four or five inches of the ligaments are exposed. The abdomen is then opened in the usual way in the median line, adhesions, if any exist, are broken up and the uterus is replaced. An incision is made in the peritoneum over the round ligaments on each side about one-half inch long and about one inch from the uterine attachments. The ligaments are found, and, as they have been separated from their peritoneal coverings, they can be pulled out through the incisions without difficulty. The peritoneal incisions are closed with Lembert sutures. At the level desired on the abdominal wall on either side of the median incision a sharp forceps is pushed through the structures obliquely, and the ligaments are grasped by the end and pulled through the wall. They are now anchored to the fascia, leaving the requisite length to hold the uterus in its normal position both as to its vertical and its horizontal planes. The abdominal incision is closed as usual. The free ends of the round ligaments are brought across and sewed together, the excess in length being cut off. The external rings are sutured and the skin is brought back and sutured with a subcutaneous stitch. The points of advantage in the operation are that it supplies a natural and sufficient support to the uterus both during quiescence and during pregnancy. During pregnancy, the ligaments will grow and lengthen out as the uterus grows, and after pregnancy will undergo involution with the uterus, so that, theoretically at least, the backward displacement will not recur. The suspension of the uterus is by the round ligaments alone with no peritoneal adhesions to hamper enlargement and involution. By transplanting the ligaments the uterus can be held in exactly the position desired. No trap is set for the intestines, and there is no pulling on the internal ring, or wedge of peritoneum in the way, to increase the tendency to hernia.

18 Phases in the Development of Therapy. A. Jacobi, New York.
19 *The Gopher; a Possible Substitute for the Guinea-pig. S. W. Hewetson, Pincher Creek, Alberta, Canada.
20 *Mammary Syphilis, with Involvement of the Axillary and Supraclavicular Glands, Simulating Cancer of the Breast. E. Beer, New York.
21 *Diagnosis and Treatment of Anemia. H. Brooks, New York.
22 Gastric Dilatation. A. G. Hurdman, Denver, Colo.
23 Adenoids: the Cause of Children's Disease Most Frequently Overlooked. J. A. Donovan, Butte, Montana.

19. **The Gopher.**—Hewetson has considered the gopher as a possible substitute for the guinea-pig in laboratory experimentation. He has found that the gopher is extremely susceptible to tuberculosis, thus placing in the hands of medical men residing in the gopher belt an additional aid in the diagnosis of obscure cases.

20. **Mammary Syphilis Simulating Breast Cancer.**—Beer's patient, a woman, aged 35, noticed about four months prior to the examination a mass in her left axilla. A few weeks later she noticed a similar mass in the upper half of the left breast. These tumors caused neither inconvenience nor pain. The tumor in the upper half of the left breast measured 2 by 3 inches. It was not tender. It was freely movable on the deeper parts and non-attached to the skin. Its border was indistinct, its surface smooth, and its consistency moderately soft but not fluctuating. The nipple was normal. In the region directly below the middle of the left clavicle there was a similar mass apparently lying below the pectoralis major muscle and pushing this forward. This mass was about half the size of the tumor in the breast. Its borders were more distinct, and it felt rather spherical. In the left axilla there was another soft mass, almost the size of a hen's egg. It was freely movable and non-tender. In the same axilla there were a number of other enlarged glands. All these were of the consistency of inflamed glands. In the left supraclavicular region another similar mass fully as large as a hen's egg and several small glands of the consistency of chronically inflamed glands could be felt. The large mass in the supraclavicular region corresponded in all of its characteristics to that in the axilla. In the right axilla and right supraclavicular region there were a number of enlarged lymph nodes of normal consistency. On both sides of the neck the posterior cervical lymph-node chains were enlarged and distinctly palpable. Otherwise the patient showed nothing. The consistency of the tumor and the presence of the enlarged posterior cervical lymph nodes suggested the diagnosis of mammary syphilis. The patient was put on antisyphilitic treatment, with the result that all the tumors and enlargements disappeared.

21. **Anemia.**—Brooks emphasizes the following points: 1. The most important step in the study and treatment of resistant anemia is first a thorough and complete examination of each case in its every aspect. 2. The technical difficulties of such an examination are not great, and the results more than repay the time required. 3. Both clinical and laboratory methods must be used and the united evidence impartially considered. 4. The treatment of anemia must be based, first, on a thorough study of the particular case in hand. 5. Greater results are to be expected by the employment of carefully considered hygienic methods than from the use of drugs alone. 6. Little or nothing of value has been recently added to the purely medical treatment of the anemias.

25 *Review of the End Results in Cases of Exophthalmic Goiter Treated Surgically. T. W. Huntington, San Francisco.
26 Use of Ether in Medicine—The Treatment of Neurasthenia by Intermolecular Baths of Polarized Ether. W. Rollins, Boston.
27 Mercuro-Cataphoresis in Diseases of Women. F. C. Carleton, Boston.

24. **Organization of a Department of Clinical Medicine.**—Cabot and Locke claim that, given good teachers and abundant material for teaching, the benefits acquired by the student can be enormously increased by good methods of instruction or diminished by poor ones. During the past ten years Harvard, with essentially the same teachers and the same material, has added appreciably to the acquirement of her students by the gradual development of a better system of instruction. In their opinion, there are four chief methods of teaching medicine, and they should come in the following order: 1. Tell the student what he is to do. (Didactic or introductory lectures.) 2. Let him watch the instructor do it. (Amphitheater "clinics.") 3. Let him practice it under the teacher's direction. (Section teaching.) 4. Give him the opportunity to be of use by doing it himself under general supervision. (Ward work and out-patient work.) Each of these four processes is to be further subdivided with reference to the three main branches of every subject that is worth teaching, viz., observation, record and reasoning. 1. The student must be told how to observe, how to record his facts, how to reason with medical data. 2. He must watch his teacher in the act of studying cases, recording data and working up those data by reasoning. 3. He must himself practice examining patients, keeping records and reasoning from them under close supervision in small sections—clinics or quizzes. 4. He must be set to work quasi-independently to be of use as a physician himself, first, in the study and care of patients in the wards and dispensaries; second, in the investigation of disease by the collection of cases, reading and experimentation, the whole to be put together as a graduation thesis. Finally, the authors emphasize the need of greater diversity in the methods of teaching, of more drill in the proper keeping of records and of a broader training in the use of literature, more section work, the wider use of pictures in teaching, increase in the amount of independent work, adequate supervision, correlation and criticism of the teaching, and examinations on the ability to practice medicine rather than to write or talk it.

25. **Surgery in Exophthalmic Goiter.**—Huntington has treated surgically nine cases. In each instance partial ablation of one or both lobes of the thyroid was done, and one patient was subjected to three operations successfully. Seven patients were females and two were males. Their ages ranged from 28 to 56. In five patients there was pre-existing enlargement of the thyroid. In four the development of characteristic symptoms was simultaneous with glandular hypertrophy—all of these were colloid. In the five cases in which the exophthalmic condition developed secondarily, pre-existing glandular hypertrophy was noted during a period of six, ten, thirty-four, thirty-five and thirteen years, respectively. In this series, exophthalmic symptoms had been noted one, two, three, two and two years prior to operation—average one and four-fifths years. Duration of symptoms in the primary or pure Basedow cases prior to operation was two years, three months, two months and one year—average, seven and one-quarter months. Bilateral thyroid hypertrophy was noted in every case. In two it was recorded as slight. In four it was clearly noticeable, and in three the enlargement was exaggerated. The two cases of longest duration, thirty-four and thirty-five years, were of the cystic variety. Exophthalmos was manifest in eight patients. In four this symptom was recorded as slight, in two distressing, in two exaggerated, and in one absent. Tachycardia in varying degree was present in every case, and in four instances it was so manifest as to throw serious doubt on the propriety of surgical interference. Vascular disturbances, with associated symptoms, such as pulsation of cervical veins; arterial hum in the carotids and branches; interference with the sympathetic system manifest in abnormal glandular activity; in profuse perspiration; hyperemia, local or general; alternate dryness and excessive moisture of the palms and soles; polyuria; digestive disturbances manifest in occasional attacks of diarrhea were present in nearly every case. Psychic disturbances and neuroses of a somewhat vague character, which may be described as temperamental changes, undue excitability, intolerance of noise, weeping without adequate cause, capricious appetite, and the development of strong dislike for friends and relatives, was noted in more than half the cases. Two of the patients had experienced frequent well-defined suicidal impulses. Dyspnea of mechanical origin was uniformly present: slight in four and distressing in five cases. Deglutition was interfered with to a greater or less degree in seven cases. Muscular weakness, especially in the musculature of the thighs and back, was of frequent occurrence. In the first case, ether was employed as an anesthetic throughout the entire procedure. In the following three cases, nerve trunk cocainization was employed satisfactorily. In the last five cases, Schleich's method was followed and found to be, on the whole, satisfactory. Eight patients survived the operation and are now living. One patient died on the twelfth day.

34. **Conservative Treatment of Chronic Suppurative Frontal Sinusitis.**—According to Casselberry, the demand for radical and surgical interference is imperative when there are actually present symptoms of commencing intracranial infection, such as severe persistent headache, chills, fever, central paralysis, etc., but the mere indefinite chance of complications of this kind does not warrant an external operation without additional valid reasons, inasmuch as one risk may be said to balance the other. Hence, the intranasal or conservative methods are especially suitable for latent and mildly chronic uncomplicated single sinus suppurations. Casselberry reports sixteen cases treated on the conservative plan. Six cases were of a mild type, and these patients are now well. Of the remaining ten, typically severe cases, only one patient can be called cured, two are much improved, suffering but little in-

convenience, three more are somewhat improved but are still sufferers, and the remaining four are unbenefited. In five cases there was no continuous discharge, but severe, subacute attacks were repeated every eight or nine months until the middle turbinated bodies were reduced by deep cauterization, when the attack ceased for a period of 11 years, with but one trifling recurrence. One patient had only an intermittently conspicuous discharge. Irrigation of the left frontal sinus, after middle turbinectomy, evacuated pus. The discharge gradually lessened and finally stopped. Three cases of multiple sinusitis were helped by drainage established by means of middle turbinectomies, curettage and irrigation. In three cases, the treatment was interrupted too early, and, while benefit accrued, it was far from a cure. Three patients were not benefited by intranasal treatment, but rejected the external operation. In two cases syphilis was the underlying cause, yet antisyphilitic treatments had little influence. Casselberry advises that in these cases radical treatment should not be deferred too long.

43. **Nose and Ear Complications in Diphtheria, Scarlatina and Measles.**—The points emphasized by McCollom are (1) the frequency of otitis media in diphtheria, scarlet fever and measles, (2) the importance of early operation, mastoiditis occurring in these diseases, (3) the necessity of frequent examination of the ears when there are no symptoms referable to these organs, and (4) early incision of the drumhead in the acute and infectious diseases.

46. **Laryngeal Syphilis Requiring Tracheotomy.**—Theisen's patient had been inoculated with syphilis by her husband. The symptom for which she sought relief was a gradually increasing dyspnea. On examination the nose and nasal pharynx were found normal, with the exception of a slight nasopharyngeal catarrh. The entire epiglottis was infiltrated and pulled back to such an extent that the laryngeal entrance was practically closed. There were no ulcerations. The glottis, with the exception of a very small opening posteriorly, was closed by a mass of cicatricial tissue stretching from side to side just under the vocal cords. The attacks of dyspnea became so frequent that it became necessary to perform a low tracheotomy under local anesthesia. Since then the gain in the patient's general condition has been quite remarkable. She is still wearing the tracheotomy tube. Theisen favors intubation in cases in which the stenosis is not extreme and when it is caused by a thickening and infiltration of the cords and ventricular bands, thus narrowing the glottis. In some such cases intubation may be carefully used without preliminary tracheotomy. When the stenosis is extreme, however, or when membranous adhesions exist between the cords, leaving only a very small opening, a tracheotomy should precede attempts to dilate the stricture from above. In such cases a sudden edema may prove fatal before an intubation tube could be properly adjusted. Tracheotomy, followed by laryngeal fissure, offers the best chances of a permanent cure when there is much cicatricial tissue occluding the glottis by uniting the cords.

54 *New Points of Least Resistance in the Consumption Diathesis. T. J. Mays, Philadelphia.
55 *Skiagraphy of the Stomach and Intestines. H. Hulst, Grand Rapids, Mich.

54. **New Points in Consumption Diathesis.**—May's contribution consists of a study of the vagus reflex in 380 individuals, 138 of whom were consumptives, and in 97 per cent. of these the reflex and the pulmonary affections were found on the same side, and in 3 per cent. on opposite sides—thus being present in every case of consumption. The rest, or 242 persons, were healthy, and of these 117 showed either a vagus reflex or a family history of pulmonary consumption. In 94, or 80 per cent., of the 117 individuals, the vagus reflex and a family history of consumption coexisted in the same person; in 14, or 12.38 per cent., a family history of consumption (which was rather remote in 4) was not accompanied by a vagus reflex; and in 9 patients (three of whom had an alcoholic and 2 an insane ancestry), or 7.96 per cent., the vagus reflex was present without a family history of consumption. In the remaining 125, or about 50 per cent. of these (242) there was complete absence of a family history of consumption and vagus reflex. From this investigation the following conclusions are drawn: 1. The vagus reflex is always present in pulmonary consumption. 2. The vagus reflex is present in about 80 per cent. of healthy people who have a family history of consumption. 3. In healthy persons without a family history of consumption the vagus reflex is universally absent, provided there is no family or personal taint of alcoholism, insanity, or other neuroses. 4. In the development of the vagus reflex dizziness, dyspnea, coughing and sweating are produced. 5. The intensity of the vagus reflex or, in other words, the number of symptoms that accompany its development other than those which manifest themselves locally in the neck, seems to be depenedent on the number of consumptive deaths that have occurred in the immediate family. 6. The vagus reflex, by projecting the family history of the potential consumptive into the present, not only becomes a valuable sign in the diagnosis and prognosis of pulmonary consumption, but foreshadows that which is not otherwise evident to the senses, and thus also becomes an important factor in the prophylaxis and treatment of this disease.

55. **Skiagraphy of Stomach and Intestines.**—Hulst's experience in skiagraphy of the stomach and intestines is limited to 22 cases, but these have been amply sufficient to demonstrate to him the value of the method. One ounce of bismuth subnitrate is suspended in one quart of milk and eaten slowly with or without bread. It is important that the bismuth be free from arsenic when such large quantities are given. The first skiagraph is taken immediately or soon after the bismuth meal. In from four and one-half to six hours the normal stomach passes the bismuth on, if no food is taken meanwhile. The second skiagraph should be taken in about six hours and no food allowed between. If food is taken the remaining bismuth, getting mixed with it, is kept in the stomach that much longer. From twelve to forty-eight hours after the meal is the best time to obtain a good picture of the colon, the length of time seeming to be in direct proportion to the degree of constipation present. The anticathode should be accurately centered over the part of the spine directly opposite the umbilicus. The latter, if desired, may be indicated on the plate by sticking a penny on the navel. The distance of the anticathode from the plate should be twenty inches. By observing these two precautions the data obtained from the resulting skiagraphs can serve as a basis for comparison, although they have no orthodiagrammatic value. To get a good view of the pelvis as well, it is necessary to skiagraph the subject standing up. The patient not being exceedingly corpulent, the exposure, with a tube at twenty inches and a good diaphragm, can be made easily in ten seconds, and in even considerably less time, with from 10 to 20 milliamperes going through the tube. Other things being equal, the shorter the exposure the better, on account of peristalsis. The pictures of the normal stomach and colon obtained in this way are at variance with the illustrations and descriptions contained in text-books on anatomy. Hulst believes that this matter ought to be investigated carefully by the anatomist with a view to correcting the existing misconceptions. He concludes by saying that if it is true, as has been claimed, that it is often of more importance in cases of heart disease to examine the abdomen than to distinguish the fine point of the auscultatory symptoms, because relieving gastroptosis may mean relief of the heart, if prolapse of the abdominal organs is only half as common as our best internists now believe, and especially if the condition of ptosis and dilatation is the cause of suffering, chiefly of women, attributed to it, the skiagraphic examination of the abdomen as attempted in this article can not fail to add something of value to the other exact methods of diagnosis.

1. **Medical Education in London.**—In this paper Allbutt discusses education versus instruction; preliminary education as obtained in the public schools; university instruction and its value in expanding and enlarging the mind, making it a more and more perfect instrument of knowledge and progress; the needs of medicine; the overloading of the medical curriculum, teaching many studies ill rather than a few studies well; the facilities for postgraduate study and research work, and the ethics and outlook of the medical profession.

2. **Rand Miners' Phthisis.**—Under this title Oliver describes a form of phthisis prevalent among the Rand gold miners. It is due to the inhalation of a fine dust that rises during the dislodgment and breaking up of stone by the use of explosives and the shoveling aside of débris of fallen stone. The essential pathologic feature of this variety of phthisis is the formation and retraction of fibrous tissue of a low type. The disease once developed, is seldom interrupted; it tends to become progressive. A peculiar bronzing of the skin and shortness of breath are the two prominent symptoms of this affection. One of the distinctions between gold miners' phthisis, or silicosis, and ordinary tuberculous phthisis is that in miners' phthisis a man does not feel that he is really ill until he is, practically speaking, past all work, whereas in the tuberculous form the patient is often ill long before there is any extensive disease in the lung, owing to the fact that toxins are secreted by the tubercle bacilli, while there is no soluble poison in miners' phthisis. There is no medicine or combination of medicines that will check the onward course of the disease once it is fully established. Cod-liver oil, nux vomica and potassium iodid, liquor strychniæ, calcium glycerophosphates or the hypophosphites will help to maintain the general health, but the best treatment of all is for men not to work too long at rock drilling, to work fewer hours a day than they have been doing, and on the first indications of failing health and strength to give up the work and seek for a life in the open.

3. **Pulmonary Atelectasis in Adults.**—Huggard states that atelectasis, in so far as it affects a small portion of lung in adults, is an extremely common condition at the apex, but is overlooked owing to the ordinary method of examining the chest. The usual physical signs are dullness on percussion with feeble breath sounds, the dullness diminishing or passing off after a few deep breaths, the breath sounds at the same time becoming more distinct. A few sticky or viscid râles can often be heard toward the end of the first two or three deep breaths, but they get gradually fainter and then disappear. The signs of atelectasis may reappear with extraordinary rapidity. The most frequent seats of affection are, first, from the apex to the second interspace in front; next, the suprascapular, and then the interscapular region. The primary ailment must be attended to. For the condition itself, systematic deep breathing must be employed; for example, deep respira-

tions should be taken for a few minutes every hour. If there are no contraindications, exercise to develop the chest muscles is advisable. The patient must be careful to avoid anything, whether clothing or a cramped position, that might interfere with the free expansion of the chest.

4. **Tracheotomy Under Local Anesthesia.**—In 9 cases Thomson performed tracheotomy under local anesthesia. A tablet containing one-fifth grain of cocain hydrochlorid, one-fiftieth grain of morphin hydrochlorid and one-fifth grain of sodium chlorid is dissolved in 56 minims of sterilized water. To this is added a 1 to 1,000 solution of adrenalin chlorid in the proportion of one drop to every fifteen of the solution so that 4 minims of adrenalin would be contained in 60 minims of the prepared fluid. The skin over the trachea having been sterilized, a drop of pure carbolic acid is deposited on it at the two extremities of the proposed incision. The slight eschars produced are useful guides in indicating the situation and extent of the incision through the skin, and they render it so insensitive that the first prick of the needle is hardly felt. The anesthesia produced is complete and there is no danger of hemorrhage. Thomson performed these tracheotomies for cancer of the larynx, cancer of the esophagus, tuberculous laryngitis, lupus of the larynx, tertiary syphilis of the larynx, and malignant disease of the thyroid gland.

5. **Traumatic Pneumonia.**—The interest of Beadnell's case centers in the fact that a severe blow over the left lung of a robust and temperate young man was followed, some few hours later, by the onset of a definite left-sided pneumonia. There was no history of chill from exposure to wet or cold or of any previous attack of the malady. The weather had been perfect, and pneumonia was not prevalent; in a word, no predisposing influence other than traumatism was known to be present.

8. **Colloid Carcinoma.**—Milne reports a case of colloid carcinoma occurring in a boy 12 years old. The patient first complained of abdominal pain. This was followed by vomiting and diarrhea, restlessness and low delirium. About 13 hours after the appearance of the first symptom the patient was in collapse, the aspect being that of abdominal disease. Warmth, stimulants and turpentine enemata were applied and ergot and morphin were administered. The patient died that night. The autopsy disclosed a much distended large intestine, the contents consisting of gas and a dirty brown fluid. In the upper part of the rectum was a hard mass which consisted of a concentric growth in the rectal wall extending for two inches along the rectum and constricting its cavity. There were several enlarged glands behind this mass. The intestinal wall was thickened, while the mucous membrane was eroded and ecchymotic. Pathologic examination demonstrated that the growth was a colloid carcinoma of the large intestine.

10. See abstract in THE JOURNAL, Sept. 23, 1905, page 947.

11. **Poisoning from Sardines.**—In the case reported by Caiger vomiting and diarrhea were absent and coma was the prominent symptom, the coma appearing about 18 hours after the ingestion of the sardines. The patient died.

14. **Exaltation and Reduction of Blood Coagulability.**—Wright and Paramore have investigated the accelerating effect produced on the blood by the ingestion of calcium chlorid, calcium lactate, magnesium carbonate, milk and other medicinal agents.

15. **Diver's Paralysis.**—White and Bainbridge report a case of diver's paralysis occurring in a man, 38 years of age, who had been a diver for fifteen years. The symptoms presented were typical of the affection. The man was under observation for several years, and death finally ensued, with symptoms of pulmonary tuberculosis and cirrhosis of the liver predominant. The autopsy confirmed this diagnosis. The brain and spinal cord were removed from the body about 24 hours after death, and they appeared normal to the naked eye. The cord was hardened for six weeks in a mixture of 3 per cent. bichromate of potassium and 10 per cent. formalin; pieces from different levels of the cord were imbedded in paraffin. The staining methods used were those of Marchi and Weigert-Pal; anilin blue-black was also employed. The white matter showed no morbid changes either by Marchi's method or by the Weigert-Pal method. Throughout its entire length the periphery of the white matter presented a vacuolated appearance; this was due, however, to postmortem changes. A large number of sections of the grey matter from different parts of the cord were examined; many of them were cut serially. They appeared to show that the cells in the lumbar region were fewer in number than usual; the deficiency was most marked in the case of the large cells of the anterior horns. The cells which were present looked healthy, the only exception being that some who saw the sections thought one or two cells showed slight necrosis. The perivascular spaces in the lumbar region were larger than those in the thoracic or cervical regions. Since sections from all parts of the cord were treated in precisely the same way, the larger perivascular spaces in the lumbar region could not be due to shrinkage of the vessels. There was definite thickening of the small arteries in both the grey and the white matter; the patient had been a drinker. No hemorrhages were observed.

20. **Method of Sterilizing Sponges.**—Andrewes uses a solution of persulphate of ammonium for sterilizing sea sponges used in surgery. The exact mixture advocated is made up as follows: Thirty-seven grams of ammonium persulphate are dissolved in 950 c.c. of pure distilled water and 11 c.c. of strong hydrochloric acid are then added. When first made up, the mixture has no very extraordinary germicidal powers, but in the course of a few days these become very pronounced, and when six days old the mixture will kill anthrax spores in less than one minute. It retains its efficiency for many weeks. It is a perfectly clear, colorless solution, with no staining powers and no injurious action on the skin, though it may fix blood stains in the crevices of the nails. Some of the methods in common use for the preparation of sponges for surgical purposes occupy several days. By this method they can be sterilized with certainty in an hour, whereby considerable economy in the stock of sponges required can be effected. Moreover, discolored sponges can be bleached and renovated. For this latter purpose a sojourn of two or three days in the mixture is requisite. For mere sterilization, an hour is ample; the sponges should then be rinsed in sterile water and stored in carbolic solution. This is advisable because the persulphate does exercise a certain injurious effect on their texture. Andrewes found that if they are kept soaking in the mixture for three or four weeks they become softened and eventually disintegrate; hence, the shorter the sojourn at each sterilization the longer will be the life of the sponge. He emphasizes two facts in connection with this method. First, the persulphate mixture should have been made up at least four days before use, but preferably not more than a month. Second, the method does not do away with the necessity for preliminary mechanical cleansing of the most thorough kind to get rid of all fibrin and other organic matter in the interstices of the sponge. The expense of the method is slight—a gallon of the persulphate mixture costs less than 25 cents.

28 *Du traitement du lupus ulcéré et de quelques autres manifestations tuberculeuses par l'héliothérapie. Vidal.

24. **Removal of Stomach.**—Boeckel reports a second case of almost total gastrectomy on account of cancer. His first patient lived for seven and a half months after removal of the stomach and then succumbed to the effects of intestinal occlusion. The autopsy showed that there was no trace of recurrence of the cancer nor of metastasis. The patient had been in good health during the interim, eating ordinary food and digesting better than many other persons. The possibility of good health after total removal of the stomach is further corroborated by the present case. The patient was a man of 43, and the cancer in the lesser curvature occupied almost the entire cavity of the stomach. The organ was entirely removed below the cardia and the duodenum sutured to the latter. The patient was dismissed, quite recovered in three weeks, having gained 13 pounds. Boeckel reviews 48 published cases of removal of the stomach on account of cancer or (in 3) of plastic linitis. The mortality was 39.1 per cent., but two-thirds of the deaths were due to peritonitis, and in the others to shock or to pneumonia. Out of the 28 individuals reported cured, 21 have been followed to date, and recurrence was observed in 11 (before the second year in 7, and between this and five years in the others). Two of the 22 succumbed to an intercurrent affection, and 8 are living in good health, 2 for more than a year, 5 between two and five years, and 1 for more than eleven years. In every instance the cancer was in an advanced stage.

25. **Infections and Intoxication from Meat.**—Babes writes from Bucharest to suggest that certain diseases observed in human beings are traceable to meat from animals affected with similar infectious diseases, due principally to microbes intermediate between Eberth's and the colon bacillus. The principal characteristics of this group are the great virulence of the germs, the production of toxins which resist high temperatures, and the ability to produce infection by way of the digestive tract. He gives a number of instances of epidemics from this source and queries whether it is not responsible for a whole series of human affections, such as paratyphoid, certain cases of typhoid, dysentery, different cases of cholera morbus, of enteritis, of septicemias, of hemorrhagic affections, and of bronchial, pulmonary, gastrointestinal and hepatic infections of obscure origin, of Weil's disease, and of infectious myelitis, in all of which he has succeeded in isolating microbes resembling in every respect the *Bacillus enteritidis* by Gaertner or the paratyphoid bacillus. Serodiagnosis should not be considered complete unless made with these bacilli as well as the typhoid bacillus.

27. **Urgency for Detecting Tuberculosis Among the People.**—Vidal urges that all medical certificates issued to wet nurses, school children, etc., should include a clause testifying to the condition of the individual's lungs. All government employes should be inspected by a physician at certain intervals to detect incipient tuberculosis, and every person consulting a dispensary or entering a hospital, presenting any indications of tuberculosis, should be reported to some central office where a register should be kept of all cases of tuberculosis. Measures should be taken to protect and to cure patients in the incipient stage and to prevent infection of others.

28. **Cure of Surgical Tuberculosis by Exposure to Sunlight.**—Vidal practices at Hyères, on the southern coast of France, and here reports 8 cases of patients with ulcerating lupus or with tuberculous ulcerations in the neck or tuberculous arthritis of the knees, all cured by systematic exposure to the direct sunlight for several hours a day. In some of the cases all previous measures had been ineffectual.

36 Resolutions Adopted by International Tuberculosis Congress. Paris, October 7.

29. **Tuberculosis in Dogs.**—Landouzy states that the museum annex to the Tuberculosis Congress contained an exhibit of tuberculous lesions found in dogs, with statistics showing the frequency of the disease among them. One veterinary school reported that the proportion of tuberculous dogs has increased from 4.5 to 9 per cent. during the last five years. Several of the specimens exhibited were of tuberculous ulcers on the muzzle and elsewhere. Some were from dogs that had been pets of noted persons. He adds that the dog tuberculized by man is another example of the diffusion of the tubercle bacilli by promiscuous expectoration. The tuberculous dog, playing with the children, licking their faces, licking the hands of his master, may recommence the cycle of infection. In conclusion he remarks that all danger from this source can be avoided by rigid measures to prohibit promiscuous expectoration and to destroy all virulent bacillary material in the houses and to enforce the use of closed garbage cans in which dogs are unable to forage.

30. **Tuberculosis in Laundry Workers.**—Landouzy has had opportunity to examine 1,590 laundry employes treated at the Laennec Hospital, this class forming fully 6 per cent. of the 23,249 inmates of the hospital between 1900 and 1904. More than a third of the 1,202 women and more than a half of the 388 men were affected with pulmonary tuberculosis, generally of the acute form. Surgical tuberculous lesions were rare among them. Laundry employes, as a rule, are young and strong, but they become infected from breathing the dried sputa from handkerchiefs, napkins and bed linen. All these articles are sorted out, pell-mell, and the employes live and breathe in an atmosphere full of bacillus dust. He pointed out long ago that attendants in hospitals have much less to fear from eruptive diseases, diphtheria or typhoid fever than from dry sweeping of the wards and halls, and that postoffice clerks employed out of doors are much less subject to tuberculosis than those employed in the postoffices where dust is being constantly brought in and stirred up by the public. Also that policemen are in much less danger from the bullets of bandits than from the promiscuous expectoration on the floors of the police stations. In the same line he now points out that laundry employes run much less risk from pneumonia, etc., than from their manipulation of dry handkerchiefs, napkins, pillow cases and sheets. He adds that this professional tuberculosis of laundry workers may entail endemic tuberculosis. Sanitary certificates should be insisted on for every house, and they should state the profession of its inmates or late residents. If they include a laundry worker, the house should be mistrusted until disinfected. Tuberculosis among laundry workers is avoidable, and education of the public will certainly reduce its proportions. Education, he adds, will foster the fear of contagion, and the spittoon will be generally adopted, just as the custom of using a handkerchief when blowing the nose was introduced into France in the days of Henry III. When the fear of contagion is once implanted, protective measures will become mere ordinary reflex actions. The task of educating the public belongs to physicians. They must make families understand that they have duties to perform, and chief among them is the obligation to render harmless the virulent expectorated matters and to take care of soiled linen differently from the present customs. Laundry workers should be protected by sanitary regulations, enforced by public authority if need be.

32. **Tuberculosis of the Kidneys and "Experimental Polyuria."**—Albarran lost only one patient in 64 on whom he performed nephrectomy, and regards it as scarcely a dangerous operation. Nine of his patients, operated on more than six years ago, and 2 more than ten years ago, are known to be in good health to-day. The general health improved remarkably after the nephrectomy in every instance, and the secondary cystitis was much improved or cured by the operation. The cystitis always heals when it is due to mere irritation of the bladder, but if the tuberculous lesions in the bladder are in an advanced stage cure is dubious. Without operation, tubercu-

losis of the kidney entails inevitably the destruction of the organ. Even if the process heals, stenosis or obliteration of the ureter is unavoidable. The only contraindications to nephrectomy are insufficiency of the other kidney and bad general condition. The early signs are usually merely disturbances in urination and changes in the urine, occasionally accompanied by general debility and pain in the kidney. Absence of micro-organisms in a purulent urine should suggest the possibility of renal tuberculosis. He refers to a work he has published recently on the exploration of the kidney functions, summarizing his views in the statement that intravesical segregation of the urine, cryoscopy, phloridzin glycosuria and the methylene-blue test are all more or less unreliable. He found that methylene blue can be eliminated apparently normally when both kidneys are diseased, and even when one of the kidneys is profoundly affected with tuberculosis with large cavities. Catheterization of the ureters for from fifteen to thirty minutes is also unreliable. He asserts that the only means of obtaining absolutely reliable information in regard to the functional capacity of the kidneys is by what he calls "experimental polyuria." This consists in comparing the rate of spontaneous and induced elimination of urine by the two kidneys in a series of samples successively collected by catheterization of the ureters before and after the induction of polyuria by ingestion of water. By this measure it becomes possible to study microscopically and chemically the urine from each kidney and to determine the working capacity of each organ. In possession of data thus obtained, the surgeon is able to make a diagnosis with certainty in the early stages and to establish the prognosis of surgical intervention on a solid basis, thus sparing the patient the dangers of temporization.

38. **Present Status of Our Knowledge in Regard to Tuberculosis.**—Cheinisse has been an attentive attendant at all the European tuberculosis congresses. He summarizes the work of the International Congress, which has just closed its sessions at Paris, in the statement that it has not added to our knowledge in regard to tuberculosis, except possibly in the authoritative denial of Koch's assertions in regard to the duality of human and bovine tuberculosis. He calls particular attention to the fact that, notwithstanding the great hopes based on the newer diagnostic methods that have been evolved in the laboratory, the clinic still holds its own as pre-eminent, especially in deciding a question so delicate as the early diagnosis of tuberculosis. He remarks that the very multiplicity of "serums" and "new tuberculins" proposed for the treatment of tuberculosis is an evidence that to date none of them can be regarded as specific. The lack of corroborative reports from others besides the inventors or discoverers of these serums is testimony enough, especially when, as in the case of Marmorek's serum, his confrères have been given ample opportunity to try them. Cheinisse says in regard to Behring's announcement that the profession will have to wait until the worth of his new remedy has been tested and confirmed by other scientists, both experimentally and in the clinic. Cheinisse further discusses the collaborating of the press in disseminating scientific views. This part of his article was reviewed editorially on page 1411.

39. **Direct Inspection of the Sigmoid Flexure.**—Strauss states that he has succeeded in endoscopy in 95 per cent. out of his last series of nearly 120 cases. The failures were in persons with such loose sphincters that retention of air was impossible. He applies the pneumatic principle and uses an endoscope of his own devising which, he thinks, is a great improvement over Kelly's. He gives illustrations of it and of the views obtained. In many pathologic processes, differentiation is possible only by this means. He relates a number of instances to show the value of the information thus derived. In one, for example, the flexure was spasmodically contracted, simulating a tumor, with evidences of gastroptosis. This spastic contraction of the flexure is not uncommon as an accompaniment to gastroptosis. The flexure was sensitive to pressure and the stools contained much mucus. Cancer had been surmised, but sigmoidoscopy revealed, as Strauss expected, absolutely normal conditions, and the patient is still in good health, several years afterward. In another case, hard, enlarged inguinal glands and tenderness of the flexure suggested cancer of the latter, but sigmoidoscopy was negative, and the cystoscope finally revealed a malignant neoplasm in the bladder. There had been no hematuria during the six months the patient had been under observation, only indications of mild cystitis. The contracting force of the constrictors of the flexure is much below that of the anal sphincters, and, as the rectum holds about a pint and the flexure about a quart, a quart and a half of fluid introduced will make its way into the flexure. In order to hold it there, in case the opening is relaxed, Strauss inserts a sound covered with a long, thin rubber bag with an enlargement about 3 mm. from the tip. This bag and bulb are inflated and serve to plug the opening into the flexure. He has very seldom found these mechanical procedures annoying to the patients, and now omits all attempts at local anesthesia except in special cases.

41. **Spirochetes in Syphilis.**—Mulzer reports positive findings in 55 cases of syphilis, and invariably negative findings in other affections.

42. **Nursing When Mother Has Scarlet Fever.**—Salge believes that an ordinary cold in the head, in the mother, is more dangerous for the nursing infant than scarlet fever. Infants under 6 months are practically immune, he thinks, to scarlet fever, and a preventive serum injection would protect them in case of diphtheria. Breast milk confers the best protection against infections, and there is no reason for taking the child away from the mother in case she exhibits an acute infection. The only disease that contraindicates nursing is tuberculosis. With this exception, the acute infections are no contraindication to breast nursing, unless the infection is of an extremely severe type, in which event the secretion of milk would probably cease. He cites a case in detail to prove the correctness of these principles. The milk secretion diminished after the onset of the escarlet fever, but it was easily supplemented by a little artificial feeding, and the amount gradually returned to normal as convalescence approached, and both mother and child were soon in fine condition. He warns expressly against the custom of wiping out the mouths of infants, as this is liable to cause erosions which invite infection.

43. **Device to Improve Percussion.**—Herz uses a small, round, air-tight box to set over the part to be percussed. A rod passes through the top and rests against the skin, and a tube enters the box, the ear tubes being connected with its two branches. The effect of percussion on the rod through the top of the box is transmitted to the ears with magnified intensity. He gives illustrations of the findings when this appliance is placed over the sternum. It enables the outline of the enlarged heart or of an aneurism, mediastinal tumor, infiltrated

part of the lung or other mass directly under the sternum to be determined with great precision.

44. **Treatment of Tuberculosis with Koch's Bacillus Emulsion.**—Pöppelmann has been using this treatment for five years and his experiences have been invariably favorable. He thinks that it is especially adapted for dispensary treatment of incipient cases. If applied on a large scale he is convinced that it would be a most important reform in the campaign against tuberculosis, stifling the disease everywhere at its inception and at trifling expense, without waiting for the red tape sanatorium treatment. He combines it with systematic frictions with some preparation of iodin and open-air reclining when possible.

48. **Injuries of the Ear in Accident Insurance.**—Baginsky urges that the specialist should be consulted at once after an injury affecting the ear. It has been his experience that only in the rarest cases does improvement develop later, and then only to a very moderate extent. There is no doubt that organic changes exist in the patients with a constant subjective and objective clinical picture. Merely functional disturbances are comparatively rare.

49. **Visual Inspection of Air Passages.**—Meyer has had occasion fully a hundred times to inspect the air passages for removal of foreign bodies, new growths or other affections. He uses Kirstein's autoscope for the purpose, and has found this direct inspection most important in his clinic for throat and nose affections. One girl suffered from rapidly recurring papillomata, but she is now completely cured of the tendency, and the tracheotomy wound has been sutured. Fifty-two sittings were required before a permanent cure was obtained. He describes the technic of direct and indirect inspection by autoscopy or with Killian's straight tubes for tracheoscopy and bronchoscopy, and relates a number of instances showing the value of the information to be derived from them in puzzling cases. In one case the bronchoscope aided in removing a wad of cotton in the right bronchus, and in another case bronchoscopy in a child of 3, still suffocating notwithstanding an opening into the trachea, showed fibrinous deposits in the air passages. The recurring deposits were removed through a tube again and again, with the final recovery of the child. In a third case, bronchoscopy in a patient suffering from gangrene of the lung revealed the presence of a piece of bone aspirated ten months previously. It was discovered in a small bronchus 40 cm. from the front teeth. Killian asserts that the time is approaching when a tampon can be applied directly through the air passages to the bleeding point in the lungs in case of hemoptysis. Whether this is ever attained or not, it is certain that the affections of the mucosa in the trachea and bronchi are now amenable to direct local treatment as much as the mucosa of the throat. Meyer asks why a tuberculous ulcer in the trachea can not be treated just as well as one of the larynx, now that direct inspection and local measures are possible.

50. **Partial Myotony in Occupation Paralysis.**—Curschmann describes with minute detail a case of Thomsen's disease with atrophy of the muscles. A previously healthy young man, a brushmaker, acquired an occupation paresis in the extensors of the right hand, while the antagonist muscles atrophied. The restriction of the atrophy to these muscles alone and the circumscribed field of the myotony render the case unusual.

51. **Photoactivity of the Blood.**—Schläpfer exposed a sensitized plate to the action of blood from rabbits after they had been long exposed to the sun. The changes in the sensitized plate convinced him that the blood possesses the property of taking in the light and giving out light energy afterward. He believes that the hemoglobin is mainly concerned in this phenomenon. He found that the blood of albino rabbits displayed this property much more than that of the colored animals. He suggests that varying photoactivity of the blood may be a factor in pathology.

52. **Physiologic and Pathologic Growth.**—Beneke remarks that this year is the semicentennial of cellular pathology, as it was in 1855 that Virchow published his famous axiom, "*Omnis cellula a cellula.*" As the natural conclusion from these principles of cellular pathology, Beneke classes all growth as physiologic and pathologic, the latter including cancers etc., the blastomas, as he calls them. The distinguishing features of physiologic growth are nutrition, function and endurance. The physiologic balance between nutrition and function, or—to express it differently—between the energy o growth and the energy of function, regulates the life cycle o the cell. When the growth is pathologic, this balance is lacking and we behold exaggerated growth with lacking functior and a lack also of durability in the individual cell. This cataplasia of the cells may be induced by irritation from without, and when the cells are once transformed under its influence the pathologic growth is liable to continue, although the casual irritation may have long since subsided.

55. **Carcinoma in Tonsil Region.**—Heidenhain comments on the bad prognosis of cancer in the pharynx. Czerny has not had a permanent cure in 47 cases, Krönlein only in 2 in 29, one seven years and one two years since the operation, and Lindenborn's summary of the literature on the subject mentions only a few isolated cases of permanent cure. Recurrence is the rule, but the operators fail to state just where the recurrence developed. Details in regard to this point might suggest improved technic. Heidenhain believes that to guard against the possibility of recurrence the operator must decide to remove the side wall of the pharynx, the musculature of the soft palate to beyond the median line, with the uvula, both pterygoid muscles, the superior constrictor of the pharynx and the pillars of the fauces—in short, the entire third of the side of the posterior wall of the pharynx. The bones from which these muscles spring must be removed with them, that is, the maxillary and pterygoid processes and the vertical plate of the palate bone. The masseter may be considered sound if the neoplasm is not adherent to the lower jaw. If it is adherent, then the masseter should be regarded with suspicion, for the carcinoma can spread along the periosteum of the lower jaw without any clinical manifestations. The more of the lower jaw that is cut away the better the oversight of the field of operation and the better opportunity for suturing the defect in the side wall of the pharynx. He has always had good success in suturing it in two or three tiers. As the submaxillary fossa always has to be scraped out, the arc incision from the corner of the mouth to the mastoid process seems preferable in all cases. He describes one case in which he operated by this technic, with fine functional results. The patient, a man of 50, now chews on the other side of his mouth and has no trouble in opening his mouth to 4 cm., chewing and swallowing. Radical procedures along these lines will certainly bring better results than the ordinary technic if the cancers can be removed while they are still small.

59. **Ulcers Above Strictures.**—Grevertz has observed 2 cases of this kind at Chaux-de-Fonds, and has been making a study of the subject. It has shown that the distension of the walls of

the bowel above the constriction causes a pronounced tendency to ulcer-formation after a few days of stasis. Every obstruction in the intestines and every case of ileus should suggest the possibility of danger from this source. It is another argument in favor of early operative intervention to empty the intestine.

60. **Resection of Stomach in 101 Cases of Cancer.**—Matti remarks that resection of the stomach has become a comparatively harmless intervention nowadays. The experiences at Kocher's clinic have shown that cancer of the stomach can be permanently cured. The results will grow constantly better as the cancer is diagnosed earlier and an exploratory incision made on the mere suspicion of carcinoma of the stomach. He advocates the resection with gastroduodenostomy as approximating most closely the natural conditions, while the permanent results afterward are better than with other technics. The mortality from local complications was only 8 per cent. of 75 operations between 1881 and 1904, and only 4.6 per cent. out of 43 patients operated on in the last six years. About 71.8 per cent. of 71 patients traced to date died after an interval of from one month to six years, but 20 patients, a proportion of 28.2 per cent., are still living. The average survival was 18.7 months, and the family frequently state that the patient was free from all stomach disturbances to the end. In one case of supposed recurrence the stomach proved to be free from it; the constant vomiting that had been observed was explained by the finding of retroperitoneal glandular metastases. Of the 20 surviving patients, one is in good health after sixteen years and 6 others after from eleven to five years. Recurrence in the cicatrix was observed in only one instance. Many of the permanent cures were in patients who had presented a palpable tumor, generally of the configuration of the pyloric portion of the stomach. When the stomach was artificially inflated the tumor could be felt on the right, and then it sank gradually lower as the inflation progressed until finally it approached more and more to the right costal arch and generally encroached on it for an inch or more. These changes in the position of the tumor are typically characteristic of a tumor in the pyloric region. When the tumor was in the rear of the stomach it was hidden by the progressive inflation of that organ. The difficulty of palpating a small tumor justifies investigation under anesthesia. In dubious cases, the patients should be examined several times in this way after evacuation of the intestines and stomach and inflation of the latter. Even with negative findings, if the suspicion still persists, an exploratory laparotomy may reveal a cancer, as occurred in some cases in Matti's experience. Ptosis was frequent, probably due to relaxation of the abdominal walls and of the ligaments from loss of fat. In 45 cases the motor function of the stomach was considerably impaired, while in others under lavage and diet it seemed to be nearly normal. The results of chemical examination in 80 cases were that free hydrochloric acid was absent, except in the cases in which the carcinoma had developed on the basis of a simple ulcer or in which the tumor was above the pyloric region. Lactic acid was found in the cases without free hydrochloric acid or with considerable retention. Matti's extensive monograph fills nearly 100 pages.

70. **Inhibition of Growth of Bacteria by Self-Poisoning.**—Conradi asserts that, as they grow, bacteria elaborate a certain substance which is destructive to themselves. This spontaneously-formed antiseptic is more strongly bactericidal than even carbolic acid. It does not dissolve in alcohol nor resist heat; it is diffusible, but does not pass through an earthenware filter, and seems to be of the nature of an enzyme. Its deleterious action is restricted exclusively to the micro-organisms, and he suggests the term "autotoxin" for it.

75. **Empyema of Maxillary Sinus.**—Hecht reports 2 unusual cases. In one a patient presented remarkable physical depression, multiple neuritis, disturbances in swallowing and darting pains in one ear, while convalescing from a febrile parametritis. The maxillary sinus was sensitive to pressure, but the patient rejected operative intervention, even removal of a carious tooth in that region. An ear specialist examined her twice, but decided that the pains in the ear were due to retraction of the tympanic membrane and that the disturbance in swallowing was merely a nervous reflex trouble. When an operation was finally allowed, all the disturbances were arrested. The second case was distinguished by its rapid course and the development of sudden blindness and of fatal meningitis a few days later.

76. **To Stain Sediment of Urine and Exudates.**—Wederhake commends neutral red as an excellent stain for the sediment of urine and exudates. For differentiation of wax tube casts he combines it with methylene violet. He uses a 1 per cent. solution of neutral red. One drop is sufficient, dropped on the sediment after centrifuging and decanting all the fluid down to about 1 cm. above the sediment. After shaking well, he fills up the tube with water and centrifuges again. He then decants the fluid and takes up the sediment with a pipette for inspection under the microscope. For the contrast stain he adds 20 c.c. of the 1 per cent. aqueous solution of neutral red to 10 drops of a concentrated alcoholic solution of methylene violet and uses two or three drops of this mixture. For a control stain he uses a concentrated solution of crocein scarlet 7, B, in 70 per cent. alcohol. He adds one drop of tincture of iodin to the sediment with its 1 cm. of fluid above and adds the scarlet solution to 2 cm., shaking well, centrifuging, decanting and spreading on a cover-glass. If the specimen is to be preserved he pipettes it into a drop of glycerin or Farrant's solution.

82. **Treatment of Large Pericarditic Effusions.**—To puncture the pericardium, Curschmann uses a flat cannula carrying a flat, lance-shaped cutting tip which makes a very narrow incision, while it allows thorough evacuation of the effusion. He discusses the best point for puncturing. At his clinic this varies with individual cases, but he aims to puncture as far from the heart muscle and its apex as possible, disregarding the pleura. He punctures, therefore, farther to the left than other surgeons; in case of moderate effusion, in the left mammary line, but in very large ones outside of this. The extreme limit of dullness to the left is the point chosen. Which interspace to select depends on the position of the diaphragm. After the incision has been made the cannula is left in the wound, the stopcock closed, and a tube filled with salt solution is attached to the outer end of the cannula. When the stopcock is opened, the effusion is siphoned out; the amount

of suction can be regulated. As a rule, the effusion should be evacuated very slowly. Dangerous heart weakness may be observed in case the fluid is removed too rapidly. He generally allows as much fluid to escape as can be done with unforced siphonage. The remnant of the effusion can be trusted to be spontaneously absorbed, especially if diuretics are given. Adhesions and displacement of the heart, etc., contraindicate this mode of treating pericarditic effusions. The effusion should then be tapped on the right side, with resection of ribs, if necessary.

85. **Gelatin as a Remedy for Diarrhea and as a Stomachic.**—Cohn found that diarrhea was favorably influenced when the patients took spoonfuls of a gelatin jelly systematically during the day. As his patients did not take kindly to this jelly medicine, he used gelatin that had been rendered more fluid by heating for six hours. A solution of gelatin thus prepared does not harden unless placed on ice. He doubted whether this fluid gelatin would have the same action as ordinary gelatin, but found that it surpassed the latter in its effect as an antidiarrheic and stomachic. He summarizes the results in 20 children under 2 years, in 6 under 14 and in 32 adults, all outpatients. The results were actually brilliant in certain cases and benefit was apparent in all. He prescribes the gelatin in a 10 per cent. solution, with 1 per cent. citric acid and about 9 per cent. syrup of orange peel, ordering half a tablespoonful every two hours for an infant and one or two tablespoonfuls for an adult. The results of treatment are sometimes not apparent until after 100 or 200 gm. have been taken.

91. **Hydatid Cyst in Malarial Spleen.**—After splenectomy the patient, a woman of 38, recovered rapidly. The tumor weighed 850 gm. and measured 24 by 14 cm. The woman had never suffered from any digestive disturbances and there had been no pains. The general health was good and the history of long residence in a district where the echinococcus prevailed aided in the differentiation. A distinct resonant zone was found interposed between the left margin of the cystic tumor and the inner margin of the enlarged spleen, but this resonance disappeared if the abdomen was manipulated.

92. **Endotheliomata of the Stomach.**—Cignozzi's article describes a case in detail which answers the typical description of what has been called plastic linitis, but was in reality the effects of an endothelioma in the stomach, with consecutive stenosis of the pylorus. He believes that most, if not all, of the cases of plastic linitis, in fact, belong to this category. The slow development of the trouble (6 years in Brissaud's case and 10 in Oettinger's, with 15 years in his own case), the gradual development of indications of stenosis of the pylorus, the typical picture of pyloric obstruction, vomiting of food without hematemesis and melena, the discovery of a smooth, movable tumor in the pyloric region and the absence of metastases and of cachexia, plus the anatomic findings at the operation, all are features of the so-called plastic linitis.

93. **Ascending Pneumococcus Neuritis.**—Pirrone has demonstrated by his experimental researches that the pneumococcus is able to produce an ascending neuritis, but that the nerves are not an easy route for the propagation of the inflammatory process toward the centers. The lesions grow less and less pronounced as they recede from the periphery. To reach the centers, the germs must be extremely virulent. Traumatism of the nerve centers did not seem to have any influence on the ascending neuritis.

94. **Passage of Antitoxins into Milk and Their Absorption the Alimentary Canal.**—Figari here continues his report of c perimental research in this line. He has demonstrated t not only the young, but also older and adult rabbits, when with *milk from animals* rendered immune, acquire immun to such an extent that they prove refractory to doses of toxi fatal for the controls. This proves, he thinks, that the a toxins in the milk must be absorbed in the stomach. The findings, superposed on those of his previous work in this sustain his assertions in regard to the value and the imp tance of milk from immunized animals in the treatment prophylaxis of tuberculosis. His experiments are described detail. He also gives the histories of two children presenti signs of incipient tuberculosis, who recovered complete heal while taking a quart of milk from the immunized cows ev day. The serum acquired pronounced agglutinating and ant toxic properties. He *inoculated rabbits with 5 mg. of liv* virulent cultures of tubercle bacilli to the kilogram after t months of feeding with the immunized milk. When kille later, no traces of active tuberculosis could be found in them while the controls all showed unmistakable lesions. The a *mals had all gained in weight. One of the rabbits is still li* ing, five months after the inoculation, and in good healt having increased nearly two pounds in weight.

95. **Blood Count in Affections of the Liver.**—Tonarelli reite ates that the blood count is a valuable adjuvant in diagnosi affections of the liver. In a case of epithelioma of the liver noticed low hemoglobin and pronounced oligocythemia in co *nection with hyperleucocytosis and moderate mononucleosis.*
